## TRANSIENT ATRIAL FIBRILLATION

A Frequent Occurrence in Apparently Normal Hearts

ROBERT A. CLASS Major USAF (MC)

**T**HE OCCURRENCE of atrial fibrillation in seemingly healthy persons presents many interesting problems in determining its cause and treatment. In most instances, any sizable number of individuals with atrial fibrillation can be separated without difficulty into two significantly dissimilar clinical groups—a large group with diseased hearts and a small group with anatomically normal hearts. Although it is now well known that atrial fibrillation, particularly the paroxysmal form, may occur in persons who show no other evidence of organic heart disease, the frequency with which this arrhythmia is observed in the selected and comparatively healthy military population is not generally realized.

Over 40 years ago Gossage and Broxton Hicks<sup>1</sup> focused attention upon the occurrence of atrial fibrillation in normal hearts when they reported the case of a young man who developed fibrillation with otherwise normal cardiac findings and who died 19 months later. Nearly two decades later Parkinson and Campbell<sup>2</sup> reported that 15 per cent of 200 patients with paroxysmal atrial fibrillation showed no signs of cardiac disease. Since then those familiar with this arrhythmia<sup>3-7</sup> have agreed that approximately 5 to 6 per cent of all atrial fibrillation occurs in normal hearts, the arrhythmia being transient or paroxysmal in about two thirds of the cases and established in the remainder.

---

From Clinical Medicine Branch, Professional Services Division, Office of the Surgeon, Headquarters, United States Air Forces in Europe, APO 633 New York 6, N. Y. Dr. Class is now at the Tucson Clinic, 116 North Tucson Blvd., Tucson, Ariz.

## MATERIAL AND METHODS

Sixteen cases of transient atrial fibrillation were observed during a 30 month period in military personnel stationed within an overseas command. All individuals were men on active duty with United States military forces in Europe or North Africa during the period of observation. I cared for or saw in consultation one half of the group. The remaining eight cases were obtained from a review of medical records. Each patient was examined during one or more episodes of atrial fibrillation and the diagnosis confirmed by electrocardiographic tracings. In every case a careful evaluation was conducted in order to rule out organic diseases such as rheumatic fever or hypertension as possible causes. Roentgenograms of the chest with or without cardiac fluoroscopy were obtained in each case. Laboratory studies including hemoglobin, red blood cell count, total white blood cell and differential count, urinalysis and cardiopulmonary tests were normal in all instances. In cases where hypothyroidism was suspected, basal metabolism and protein bound iodine determinations were performed with normal results. In a few other cases, a Master two step test was accomplished to evaluate the possibility of coronary artery disease.

## CASE REPORTS

Table 1 summarizes the findings in cases not discussed in detail. Only one person was over 35 years of age when the attacks began. The age at onset in five patients was 21 years or younger. Four selected case reports emphasize specific features of this condition.

**Case 1.** A 21 year old airman was admitted to the hospital complaining that "my heart is falling out of joint." Further questioning elicited a 15 year history of a sudden recurrent oppressive and aching precordial pain associated with palpitation and followed shortly by dyspnea. These attacks which had begun at six years of age were noted to be precipitated most often by physical exertion or emotional tension and excitement. They occurred at intervals from a few days to six months and were usually of a few minutes duration but one previous episode had lasted for 30 hours. During his military service the patient had been hospitalized twice previously with these attacks but they subsided without specific therapy. On both occasions the precipitating factor was emotional tension associated with a fist fight while under the influence of alcohol.

On the present occasion he had experienced a sudden onset of precordial discomfort, palpitation and dyspnea immediately following an argument. Examination revealed a hyperkinetic, excited young man with a blood pressure of 128-116 mm Hg (systolic) and 76-66 mm Hg (diastolic). The apical rate was 128 per minute and the radial pulse 120 per minute. A total irregularity of rhythm and force of cardiac systole was

observed without other abnormal cardiac findings. The remainder of the examination was not remarkable. An electrocardiogram on admission revealed atrial fibrillation without other abnormalities. He was given 0.10 gram of Seconal (brand of secobarbital sodium) and placed on bed rest, and the rhythm returned to normal 30 minutes later. A repeat electrocardiogram was interpreted as entirely normal. Basal metabolism determination was plus 4. He was returned to duty three days later with the reassurance that he did not have cardiac disease and with the advice that he avoid fights and other emotional upsets.

He was followed as an outpatient and two months later he experienced paroxysmal palpitation for a few minutes following an argument with his supervisor. One month thereafter he again experienced an episode of marked cardiac irregularity immediately after becoming excited. This subsided after 20 minutes and as usual necessitated no specific treatment.

**Case 2** A 34 year old airman was hospitalized with complaints of palpitation, nausea and vomiting for one day prior to admission while drinking excessively. During the preceding year the patient had noted transient episodes of palpitation occurring mostly at night together with mild dyspnea and sharp fleeting precordial pain unrelated to effort. He was known to be a very heavy drinker and smoked an average of 50 cigarettes per day.

At the time of admission the patient appeared acutely ill with a temperature of 98.6°F and a blood pressure of 130/85 mm Hg. His pulse was grossly irregular at 128 per minute, and respirations were 24 per minute. Examination was otherwise unremarkable except for a cardiac rate of 140 to 150 per minute with a grossly irregular rhythm. An initial electrocardiogram revealed atrial fibrillation of 110 to 160 per minute with no evidence of myocardial damage. Because of the severity of symptoms he was rapidly digitalized intravenously and eight hours later was asymptomatic but the fibrillation still persisted at 80 per minute. He was maintained on oral doses of digitalis for the next six days but the fibrillation continued with a slow ventricular rate. He was then given quinidine orally which established a normal sinus rhythm. All laboratory investigations, including cardiac fluoroscopy and basal metabolic rate, revealed no evidence of organic heart disease.

Quinidine was gradually decreased over a 10-day period, following which he was discharged asymptomatic without medication and was advised to avoid tobacco and alcohol. One month later he complained of mild palpitation. Fibrillation had returned at a rate of 130 per minute. He had resumed smoking and drinking in the interim. The arrhythmia was converted to sinus mechanism after 12 grams of quinidine given orally. Again quinidine was gradually decreased, and on return to the United States six weeks later he was asymptomatic without therapy.

**Comment** These cases illustrate the importance of emotional tension and acute alcoholism as precipitating factors and point

TABLE 1 Data on cases of transient atrial fibrillation

Case number	Age at onset	Age when first examined	Number of attacks	Duration of attacks	Possible precipitating factors	Treatment	Follow-up data
5	20	20	Several	5 min to 12 hr	Acute alcoholism and exercise	Phenobarbital	No recurrence during 6-mo period
6	32	32	1	Few hours	Heavy smoker	Quinidine abolished episode	No recurrence in 4 mo
7	34	36	3 or 4	1 to 6 hr	Alcohol heavy meals nervous tension smoked 2 to 3 packs cigarettes daily	Episodes ceased spontaneously	Unavailable
8	21	21	1	14 hr	Physical exertion	Cedilanid intravenously abolished episode	No recurrence in 2 mo
9	48	48	Several	1 to 2 hr	Smoked 2 packs cigarettes daily	Episodes ceased spontaneously	Asymptomatic recurrence noted on annual physical examination 16 mo later
10	26	29	Several	Few hours to 7 days	Upper respiratory infection and airplane flight	Quinidine abolished episode	Recurrence 6 wk after original attack Returned to duty on maintenance quinidine

TABLE 1 Data on cases of transient atrial fibrillation — Continued

Case number	Age at onset	Age when first examined	Number of attacks	Duration of attacks	Possible precipitating factors	Treatment	Follow-up data
11	28	28	1	Few hours	Influenza immunization heavy drinker (epilepsy?)	Episodes ceased spontaneously	Normal examination 4 mo later
12	17	19	Innumerable	5 min to 3 hr	Usually with emotional upsets	Episodes ceased spontaneously	Transient paroxysms continue but are not incapacitating
13	33	35	Several	Few min to 5 days	Excitation fatigue nervous tension	Episodes ceased spontaneously or with quinidine	Attacks continued over 18-mo period at intervals from weeks to several months with no suppressive quinidine therapy
14	23	23	1	Several hours	None	Quinidine abolished episode	No recurrence in 6 mo
15	20	20	1	30 hrs	Acute alcoholism	Quinidine abolished episode	No recurrence in 6 wk
16	27	27	1	3 days	Nervous tension and anxiety	Digitalis plus quinidine abolished episode	No recurrence in 3 mo

\*Cases 1 through 4 are discussed in detail under "Case Reports."

out the variability in frequency and duration of attacks. The repeated spontaneous termination of attacks in the first patient is contrasted with the longer duration of attacks requiring specific therapy in the second.

**Case 3** A 35 year old Air Force captain with 16 years of active duty was admitted to the hospital with the chief complaints of cough, diffuse chest soreness, and exertional dyspnea of one week's duration.

This officer had been in excellent health during his entire life until about one week prior to admission at which time he developed mild exertional dyspnea and cough which he attributed to a "cold." Shortly thereafter he noticed a constant aching chest discomfort without associated fever, chills, or sweating. For about two weeks prior to admission he had noted a gradual gain in weight associated with slowly increasing ankle swelling. Two nights prior to admission he experienced an episode of paroxysmal nocturnal dyspnea. The night before admission he was orthopneic and rested in a chair for the entire night. At no time had he been aware of any palpitation or irregularity of heart action.

Physical examination on admission revealed an acutely ill orthopneic white male. His oral temperature was 99°F, weight 196 pounds and blood pressure 105/85 mm Hg. There was slight neck vein distention. Cardiac examination revealed a widening of the left heart border 2 cm beyond the midclavicular line with a soft systolic blowing grade II mitral murmur. There was total irregularity of rhythm and force of cardiac systole. The apical rate was 160 and there was a pulse deficit of 80 per minute. The breath sounds were equally suppressed bilaterally and crackling inspiratory rales were audible over the lower two thirds of both lung fields. The liver was enlarged 4 cm below the costal margin in the midclavicular line and there was a 2 to 3 plus pitting edema of the lower extremities. An electrocardiogram confirmed the clinical diagnosis of atrial fibrillation and a roentgenogram of the chest revealed widening of the cardiac silhouette with bilateral pulmonary edema.

The patient was placed on bed rest with his head elevated to 70° given a low sodium diet, Mercurhydrin (brand of meralluride sodium) and ammonium chloride, and rapidly digitalized with 1.6 mg of Cedilanid (brand of lanatoside C) given in divided doses of 0.8 mg three hours apart. Eight hours after admission his apical rate had slowed to 84 per minute and there was no pulse deficit. He was less orthopneic but the left cardiac border was still widened 2 cm beyond the midclavicular line and a short soft blowing grade I systolic mitral murmur was still present. Diuresis was accomplished rapidly and by the third day his weight had decreased to 166 pounds and the pulmonary congestion had disappeared. The heart murmur was no longer audible but the atrial fibrillation was still present at a ventricular rate of 70 to 80 per minute. He was kept on 0.2 mg of digitoxin daily and given 0.2 gram of quinidine every six hours. Twenty-four hours later the rhythm had converted to

normal and he was essentially asymptomatic. A repeat roentgenogram of the chest on the fourth day following admission revealed marked decrease in the cardiac dilatation and a clearing of the pulmonary congestion.

On two occasions—once two days later and again seven months later while he was an outpatient, atrial fibrillation recurred without symptoms. On both occasions a normal sinus rhythm was restored after the dosage of quinidine was increased. He was returned to military duty and maintained on quinidine.

*Comment.* This patient's condition is a very interesting example of a prolonged attack of fibrillation resulting in pronounced congestive heart failure. It is notable that he never had symptoms such as palpitation, referable directly to the irregular and rapid cardiac rate. The original symptoms were those of congestive heart failure. He was again asymptomatic seven months later when re-examination revealed a recurrence of the fibrillation.

**Case 4.** A 35 year old Air Force captain was seen in consultation because of recurrent paroxysmal atrial fibrillation and anginal type pain of one year's duration. Prior to the onset of the present complaints he was in excellent health. The patient used no tobacco and drank only occasionally. He was accustomed to eating heavily and drinking several cups of coffee daily.

He first consulted a doctor when he experienced moderately severe, pressure type retrosternal pain which radiated to the left side of the neck and left arm and lasted for six hours. A diagnosis of probable coronary insufficiency was made on the basis of the history, clinical findings, and serial electrocardiograms. Shortly after admission he was noted to have transient episodes of atrial fibrillation which recurred both at rest and with mild exertion and was associated at times with anginal type pain. These episodes subsided spontaneously or with small doses of quinidine. The results of a basal metabolic rate, serum cholesterol, upper gastro intestinal barium study, a roentgenogram of the gallbladder and cardiac fluoroscopy were normal.

He was placed on a regimen of 0.2 gram of quinidine four times a day and returned to duty after nine weeks. Four months thereafter quinidine was discontinued and physical examination was normal except for moderate obesity (weight 210 pounds). While carrying heavy suitcases two weeks later he experienced a sudden recurrence of palpitation with total irregularity of the heart followed in a few minutes by anginal type pain. These symptoms subsided about five hours after onset following self medication with quinidine, phenobarbital and aspirin.

One month later while falling asleep he experienced two or three "heavy heartbeats" followed immediately by tight chest discomfort and onset of total cardiac irregularity. On this occasion fibrillation continued for 16 hours until admission to the hospital. Physical examination revealed a moderately ill apprehensive man with atrial fibrilla-

tion an apical rate of 140 to 150 per minute and a pulse deficit of 15 to 20 beats per minute. Blood pressure was 106/76 mm Hg weight 206 pounds height 5 feet 9 inches. The fibrillation terminated with bed rest alone shortly after admission. Subsequent electrocardiograms revealed a normal sinus rhythm with occasional ventricular ectopic beats. A double Master two step test on two occasions produced no electrocardiographic changes indicative of myocardial ischemia. Total serum cholesterol was 195 mg per 100 ml. A fasting blood sugar and an oral glucose tolerance test were normal. Following discharge from the hospital he was continued on a reducing diet and 0.2 gram of quinidine four times a day. When last seen he had lost 20 pounds by dieting and was continuing on active duty as a personnel officer.

*Comment* This patient illustrates the problem of eliminating organic heart disease as a cause of atrial fibrillation when chest pain is a presenting complaint. Although coronary disease cannot be absolutely ruled out this officer was an introspective anxious individual and the chest pain as well as the fibrillation was believed to be of functional origin.

#### DISCUSSION

All of these patients with the possible exception of case 4, fall into the category of patients previously described as having "benign" "idiopathic" "functional" or "uncomplicated" atrial fibrillation. This arrhythmia occurs commonly in apparently healthy young individuals. In my experience during this period atrial fibrillation was observed much more frequently in normal persons than in individuals with abnormal hearts. This is readily understandable since persons with organic heart disease as a cause of fibrillation are not often serving on active military duty. Master and Eichert<sup>7</sup> previously emphasized the frequency with which they observed "functional paroxysmal auricular fibrillation" in U S Navy personnel during World War II.

It should be emphasized that atrial fibrillation is a physical diagnostic sign and not a disease per se. Whenever fibrillation occurs one is obliged to evaluate all possible causes both cardiac and extracardiac including rheumatic heart disease, hypertension, hyperthyroidism, coronary disease, infection, drugs and drug sensitivity, toxic agents, metabolic imbalance, trauma, fatigue, overexertion and neurogenic and emotional factors. The primary problem is to ascertain whether the fibrillation is a secondary manifestation of underlying heart disease or whether it is a primary functional disorder occurring in an otherwise normal heart.

A most careful examination is necessary to rule out organic heart disease in patients with "functional" transient fibrillation before regarding such patients as normal. Careful auscultation is necessary to exclude the presence of mitral stenosis and roentgenographic examinations should be employed to assure that there

is no abnormality of the cardiac silhouette or abnormal prominence of the left atrium. The basal metabolic rate, protein bound iodine, and radioactive iodine uptake should be determined if hyperthyroidism is suspected. Ballistocardiography, although not performed in this series, is a valuable adjunct to electrocardiography in uncovering otherwise undetectable evidence of cardiac disease. Selinger and Levin<sup>8</sup> reported abnormal ballistocardiograms in individuals with paroxysmal atrial fibrillation who showed no apparent evidence of heart disease by all other methods of evaluation.

That atrial fibrillation occurs in normal hearts has been proved reportedly at post mortem examination.<sup>11, 12</sup> Atrial fibrillation may be a physiologic disturbance of impulse formation and conduction and not necessarily a pathologic phenomenon. There is no pathologic change in the heart characteristic of auricular fibrillation.<sup>13</sup>

The factors which may disturb physiologic function and contribute to the production of atrial fibrillation in apparently normal hearts are many: drugs, chemicals, alcohol, tobacco, and even carbon monoxide.<sup>14, 15</sup> Friedlander and Levine<sup>1</sup> advocated the theory of a "trigger" mechanism of neurogenic origin as an important basis for the inception of such attacks. This explanation would certainly seem reasonable for a large percentage of the cases observed in this group. Hanson and Rutledge<sup>12</sup> reported that attacks of paroxysmal atrial fibrillation were associated with a psychogenic or functional element in 70 per cent of their cases. In the present series, emotional strain and/or alcoholism were precipitating factors in half of the patients.

As seen in this group of cases, the symptoms associated with paroxysmal atrial fibrillation may vary from total unawareness of its presence to advanced incapacitation from congestive heart failure. Wolff,<sup>12</sup> in a detailed analysis, reported 28 of 81 cases of paroxysmal atrial fibrillation to be asymptomatic, and while most authors agree that palpitation is the most common complaint, less frequently observed symptoms are faintness, dyspnea, and weakness. Syncope, although uncommon, has been reported to be caused by associated hypotension resulting from a very rapid heart rate or, more probably, from temporary cardiac arrest just preceding or following the paroxysm of fibrillation.<sup>14</sup>

Very interesting is the association between angina pectoris and paroxysmal fibrillation. Wolff<sup>12, 13</sup> reported angina to be induced by paroxysmal fibrillation in several patients, the majority of whom also experienced angina on effort. However, most authors<sup>11-13</sup> agree that atrial fibrillation and angina due to coronary disease rarely occur together. Transient fibrillation is frequently found during early acute coronary thrombosis<sup>12, 13, 20</sup> associated

with congestive failure secondary to arteriosclerotic heart disease.<sup>11 16</sup> Case 4 is interesting in this regard because the patient experienced anginal like pain in association with transient atrial fibrillation. Also, the pain occurred both at rest and on exertion and was relieved only irregularly by nitroglycerin. Although in this case a double Master two step test was negative on two occasions it is feasible that the chest pain and the fibrillation were manifestations of coronary artery insufficiency. On the other hand, the order in which symptoms appeared in this patient suggests that the angina may be caused by the paroxysm of fibrillation itself as described by Wolff.<sup>15</sup>

### Course and prognosis

Although it is possible for paroxysmal rapid heart action to cause death due to heart failure, embolism, vascular collapse, renal failure or cardiac arrest from conversion to ventricular fibrillation or asystole, this rarely occurs in actual cases of paroxysmal atrial fibrillation unassociated with organic heart disease. It can be seen that the course of transient atrial fibrillation has no set pattern. The majority of these patients continued to experience recurrent attacks. Attacks may also become less frequent and of shorter duration or may cease entirely either spontaneously or with drug therapy.<sup>12 21</sup> In about 10 per cent of cases,<sup>2</sup> episodes of paroxysmal fibrillation may assume a progressive nature with eventual establishment of a permanent fibrillation.

Although persistent atrial fibrillation is not often damaging, Wolff<sup>15</sup> and Phillips and Levine<sup>22</sup> emphasized that this arrhythmia produces abnormal circulatory dynamics resulting in cardiac enlargement and Brill<sup>23</sup> and Phillips and Levine reported cases similar to case 3 of this series, in which frank congestive heart failure resulted from atrial fibrillation alone. The latter stated that this is a reversible type of heart failure and advocated conversion to normal sinus rhythm with quinidine (plus digitalis if necessary) to prevent irreversible cardiac enlargement and chronic congestive failure.

Authors<sup>2 6 11 24 25</sup> have commented upon the good prognosis and the benign nature of transient atrial fibrillation when no organic heart disease exists. There is a favorable prognosis for patients under 40 years of age at onset and whose attacks continue intermittently for more than two years.<sup>24</sup> Willius and Dry<sup>25</sup> found the death rate in a series of 59 patients to be similar to that of the general population. The patients reported here with one possible exception can expect a favorable future.

The capability of these individuals to perform satisfactory military duty was not appreciably impaired by the transient episodes of fibrillation. It therefore seemed reasonable to allow them

to continue on active duty. Although Master and Lickert stated that "patients with functional proximal auricular fibrillation should be discharged from the Navy or at least placed on limited duty ashore," and Englefeldt<sup>12</sup> maintained that such persons should be given restricted civilian jobs, the numerous articles on this subject almost universally agree that this cardiac arrhythmia is harmless and that it seems unwarranted to limit these persons in their activities and thus contribute to an iatrogenic cardiac disability.

### Therapy

These patients should be fully informed regarding the benign nature of their disability and urged to eliminate those precipitating factors which are associated with the attacks of fibrillation. In one third of this group no specific cardiac therapy was needed, the episodes spontaneously subsiding.

Two drugs, quinidine and digitalis, are widely used in the treatment of atrial fibrillation. However, the patient with infrequent episodes of transient fibrillation of short duration is not in need of such therapy. A rapid ventricular rate, particularly if over 150 per minute, is the most positive indication for definitive therapy, since congestive failure may ensue, vascular collapse may develop, and the liability of embolism is increased.

The young patient with atrial fibrillation is an ideal subject for quinidine therapy, which should be administered to all patients who do not revert to normal sinus rhythm within 24 hours, provided, of course, there is no sensitivity to the drug. If congestive heart failure has supervened, the patient should first be rapidly digitalized to control the rapid ventricular rate, eliminate the pulse deficit, and improve the myocardial contractility. Most cardiologists agree that quinidine should not be used before compensation is restored because attempts at conversion under such circumstances may result in a more pronounced and uncontrollable tachycardia or embolism. In many instances the fibrillation will revert to normal sinus rhythm after digitalization has restored compensation. If not, quinidine should then be given to convert the arrhythmia. After conversion is effected, the patient should be placed on a maintenance dose of 0.2 gram of quinidine three to four times daily for a few days, during which time digitalis may be discontinued. Quinidine may then be gradually decreased to a maintenance dose sufficient to prevent recurrences, or it may be discontinued. Differences of opinion exist as regards the efficiency of maintenance quinidine in the prophylaxis of recurrent atrial fibrillation. My personal preference is to recommend maintenance therapy in persons whose attacks become more frequent and of longer duration or whose episodes are associated with symptoms ensuing from tachycardia.

## SUMMARY

Sixteen young military men with transient atrial fibrillation were observed in whom no definite evidence of organic heart disease could be found. In military medicine when predominantly young men on active military duty are seen atrial fibrillation may often be the idiopathic or benign variety. However the most common causes of this arrhythmia rheumatic and arteriosclerotic heart diseases hyperthyroidism hypertension and coronary artery disease, must be ruled out.

In about 10 per cent of the patients with functional transient atrial fibrillation the episodes of arrhythmia may become progressive with eventual establishment of permanent fibrillation. The remainder either have recurrent attacks fairly regularly or the episodes may become less frequent of shorter duration or may cease entirely either spontaneously or with drug therapy.

This arrhythmia in the absence of organic heart disease is benign and has an excellent prognosis. The ability of these patients to perform satisfactory military duty is not appreciably impaired.

The patient with infrequent fibrillation of short duration and mild or no symptoms (one third of this series) requires no definitive therapy. A rapid ventricular rate, particularly if over 150 per minute, is the most positive indication for definitive therapy with digitalis and/or quinidine. All patients should be thoroughly instructed as to the benign nature of this disorder and urged to eliminate precipitating factors. Maintenance therapy with quinidine is recommended for patients whose attacks become progressively more frequent and of longer duration, and whose symptoms of an excessively rapid heart rate are pronounced.

# TRENDS IN THE MANAGEMENT OF PULMONARY TUBERCULOSIS

CARL W TEMPEL *Colonel MC USA*  
JAMES A WIER *Colonel MC USA*

**T**UBERCULOSIS is a serious problem in the United States just as it is in most nations of the world. Despite a dramatic decline in mortality of 70 per cent in the last 10 years to the current rate of about 10 per 100 000 population the morbidity rate and cost of medical care is still high. This is evidenced by the fact that 1 200 000 persons have some form of tuberculosis. 250 000 are carried on the caseload of health agencies as active cases, 86 000 persons were added to the active caseload within the past year, an estimated 150 000 persons have undetected tuberculosis, and the annual expenditures for action prevention and treatment are around six hundred million dollars.<sup>1</sup>

The availability of new effective antituberculous drugs and surgical procedures has increased the potential for the cure of tuberculous patients. Because of these advances the responsibility of the physician to utilize these new methods of treatment to the best advantage has greatly increased. For this reason it is important to review periodically trends in the management of this serious disease.

## HOSPITALIZATION AND HOME-CARE PROGRAMS

It is generally recognized by tuberculosis specialists the world over that when hospital facilities are available the patient with newly discovered active pulmonary tuberculosis should receive his initial treatment in the hospital rather than at home. In the ideal situation such treatment is best continued in a tuberculosis hospital until the disease becomes arrested or inactive that is no tuberculosis organisms are recovered from the sputum (conversion) and a noncavitary pulmonary lesion is stable for a period of from 3 to 6 months. Under less favorable circumstances it is helpful to at least hospitalize the new patient for several months to (1) secure a proper diagnosis and evaluate the individual pa-

tient, (2) educate the patient and his family as to the nature of the disease, (3) treat the patient with specific drugs until the therapeutic goal appears to be in sight, and (4) reduce the risk of contagion to members of his family and the community. Treatment in the home during the early contagious stage of the disease is difficult for the patient, hazardous for his associates and unsatisfactory from the physician's standpoint in most cases. The modern tuberculosis hospital is a complex institution with complete clinical and laboratory facilities, an elaborate radiologic department, a professional staff of internists, surgeons and consultant specialists, research workers, social workers, and rehabilitation and educational experts—all of which are essential to the successful and enduring clinical results.

Except when hospital beds are unavailable or when persons refuse hospitalization, most of the home care programs in the United States are concerned primarily with pre and posthospital treatment rather than with a planned replacement of hospital care by outpatient care. Most authorities now agree that when hospital care is unavailable for any reason, active drug therapy should nevertheless be instituted promptly. The need for prolonged prehospital treatment is diminishing in most sections of the United States as the hospital waiting lists are rapidly disappearing.

In some countries the incidence of tuberculosis is so high that hospitalization for most patients is out of the question. Under such circumstances attention must be focused on the establishment of effective health centers to conduct extensive case finding surveys and to operate outpatient services for patients undergoing treatment at home. If private physicians co-operate well with public health officials, it is possible to conduct such a program satisfactorily as long as an adequate number of public health nurses are available to visit the patient's home and to administer that phase of supervision which deals with proper isolation techniques, the evaluating of contacts, and similar phases of tuberculosis control.

#### REST THERAPY AND REHABILITATION PROGRAMS

During the past few years there has been considerable disagreement regarding the time honored measure of rest therapy, and gradual changes are being adopted. With the introduction of successful drug therapy reorientation was inevitable, but it will be some time before optimal standards can be determined. Possibly the modifications and shortening of rest treatment are proceeding too rapidly, but if so this is not yet reflected either in a slowing of the rapid rate of decline in mortality or in any definite increase in morbidity. On the contrary, the trends appear to be continuing favorably.

In July 1954 an investigation of in hospital ambulation of patients with pulmonary tuberculosis was begun at this hospital.<sup>2</sup> It is a randomized study designed to compare the results of treatment as observed during the conventional rest program with patients undergoing the ambulatory treatment regimen. The latter group do not observe rest periods and are allowed to be up and around the hospital wards and grounds near the hospital building at will. Strict isolation care is adhered to. Thus far no appreciable difference has been noted in the response of the two groups as measured by sputum conversion and by roentgenographic evidence of clearing of the lung lesions. The morale of the ambulant group is much better than in those treated with strict bed rest. The educational and rehabilitation training can begin shortly after admission and can be utilized in a better manner in the ambulant group. Inasmuch as patients take care of many of their own needs, fewer nurses and ward attendants are required to supervise the ambulatory treatment regimen. Thus far this disregard for the traditional rest program apparently has not harmed the patient. It should be pointed out, however, that these studies have been made under the close supervision of the staff of a specialized treatment center where patients are treated with antituberculous drugs to the stage of arrested or inactive disease.

Ambulation of patients with pulmonary tuberculosis under protection of chemotherapy has been reported on favorably by Dressler and associates<sup>3</sup> and less favorably by Robins and associates.<sup>4</sup> In the study by Dressler and associates conducted at the National Jewish Hospital, Denver, Colo., patients received their medical therapy in the hospital but were permitted to undergo outpatient treatment for active disease when their physical condition and home facilities permitted. Co-operation among the patients was good and the results appeared to be impressive. No control studies were made in this group.

The chief criticism of the ambulatory treatment of patients at home under unfavorable conditions is that persons with contagious stages of the disease are at large in the community. Those who oppose this type of program, however, fail to appreciate that if it were not available, most of these patients would be receiving no treatment. Such compromise must be made if hospital beds are not available or if the state or federal laws do not permit enforced treatment of the recalcitrant or unco-operative patient. The obvious answer to this difficult problem is an acceptable hospital and home care treatment program and health laws to provide adequate isolation of the patient with contagious forms of this disease. For practical purposes the latter should include all tuberculous patients with positive sputum, any person with pulmonary cavitation, patients with recently discovered active pulmonary tuberculosis and those with active disease not receiving drugs.

The rehabilitation program for tuberculous patients in hospital or at home must of necessity be planned to meet patient and community needs, and it is most difficult to formulate plans applicable for all conditions. Under most circumstances, however, it is desirable to standardize the rest and rehabilitation program. Unless this is done, personnel of tuberculosis hospitals, outpatient departments, and public health nurses will not always be acquainted with the stage of recovery of the individual patient and the treatment or training applicable for each. The physical and economic rehabilitation of the patient is receiving much attention these days because more patients are recovering than ever before and plans for their future employment are extremely important to the individual and the community. The rehabilitation program can best be administered by a classification of patients based on the activity of the lung disease and the patient's physical capacity to be restored to normal life activities and gainful employment. Such a plan has been used successfully for many years by the United States Army in the treatment program at this hospital and can be modified for civilian patients.

The basic plan of management for the patient with a new minimal lesion (active disease, 1 month) responding ideally to treatment is illustrated in table 1. Such schedules are carefully planned for each individual patient on the basis of clinical findings, but the minimum time limits should seldom be reduced. Patients with more advanced forms of the disease are treated on the same principles but their exercise status is altered more slowly, and frequently with the addition of operative procedures. To classify the patient for rehabilitation purposes the diagnosis should indicate the duration of activity and inactivity of the disease and the exercise status.

The basic rules for the management of patients with pulmonary tuberculosis are

- 1 *Bed rest and chemotherapy* are prescribed for all patients with active tuberculosis on definitive treatment and are maintained until the pulmonary lesion is found stable in serial roentgenograms for 3 months. Increased ambulation with passive privileges is then allowed.

- 2 *Ambulatory treatment* (exercise status III B) is permitted after the disease becomes inactive and the lesion is stable for 6 months. For most lesions it is desirable to use chemotherapy to this stage of disease or longer.

- 3 *Hospital care* is best used until the chest lesion is stable for from 3 to 6 months. It is desirable to defer discharge until the patient has been ambulatory for 3 months and the response (symptoms, sputum, and roentgenograms) to graded exercise has been determined. When hospital beds are not available or no

		Absent	Negative from 6 to 12 months	Stable from 6 to 17 months	II	normal life when disease is inactive 6 to 17 months restricted type of work at first and full duty or work in 7 to 8 years as judged by the physical capacity of each patient The extent of the residual disease also will be a determining factor in the type of work permitted

Based on Diagnostic Standards and Classification of Tuberculosis national Tuberculosis Association 1955 which should be consulted in formulating such plans and for definition of terms used in the table

Stable Noncavitary lesions by serial roentgenograms

needed for definitive treatment (chronic inoperable cases et cetera) home care may prove satisfactory if the patient (a) does not require specialized hospital treatment, (b) has a suitable place for his care and isolation, (c) understands tuberculosis and (d) will not be a community health problem

4 The patient may live an essentially normal life (exercise status IV) after the disease has been inactive for from 6 to 12 months except that exercise must be restricted Physical activity is then gradually increased over a 2 to 5 year period, based on an evaluation of each individual patient's physical capacity (exercise or work tolerance)

5 The same principles apply to surgical cases Patients having resections for pulmonary lesions often go home from 3 to 6 months after an operation Six months in the hospital is desirable after resection or thoracoplasty for extensive disease

### CHEMOTHERAPY AND OPERATIVE PROCEDURES

A review of the trends in the use of antituberculous drugs and the surgical treatment of tuberculosis reveals that these measures must frequently be combined for this reason certain precautions must be observed Furthermore the responsibilities of the general practitioner the internist and the thoracic surgeon in the cooperative effort to cure the tuberculous patient may be better understood if these two types of therapy are discussed together

Drug therapy of tuberculosis often produces dramatic results but it must be remembered that frequently it is not curative and must be integrated with a good rehabilitation program (table 1) as well as with operative measures (table 2) as the individual case dictates

Reversible lesions responding well to drug therapy may be treated by any effective long term drug regimen [streptomycin sulfate para aminosalicylic acid (SM PAS) streptomycin sulfate isoniazid (SM INH) and isoniazid para aminosalicylic acid (INH PAS)] without fear of future complications in the majority of the patients However when acute caseous pneumonic tuberculosis chronic fibrocaseous or fibrocavitary disease is present one must be ever mindful that drugs may not prove definitive and that surgical resection or other operative procedures may be required for the serious residuals remaining after adequate chemotherapy It should be borne in mind that the persistent cavity is the main problem in the management of tuberculosis today In the patient capable of tolerating an operation these must be treated surgically In addition to these chronic caseonodose lesions not responding satisfactorily to medical management large necrotic foci especially the residuals of recent cavitation symptomatic tuberculous bronchiectasis and the destroyed lung lobe or segment constitute lesions ordinarily beyond the definitive use of drug therapy

January 1957)

Pulmonary cavitation that does not respond to medical treatment in 6 or 8 months is not apt to disappear and the appearance of drug resistance counts after this period of chemotherapy. It has been shown in a carefully controlled study at this hospital that after utilizing our best combined drug regimen, approximately three fourths of the cavities present before the initiation of chemotherapy were still visualized in the routine roentgenogram of the chest at 4 months, 50 per cent at 6 months and 22 per cent at 8 months. With the protection of effective drug therapy, pulmonary resection was accomplished in most of the patients complicated as favorable operative risks with a very low mortality and morbidity rate. Recent reports show an overall mortality of 14 per cent in pneumonectomies, 4 per cent in lobectomies, and 1 per cent in segmental and subsegmental resections. At this hospital, where the predominant type of operation in the past two years has been resection for localized lesions, the mortality rate was less than 1 per cent. The major complication of chest surgery is the development of bronchopleural fistula but results are better under circumstances where drug protection is most effective. Complications are more of a problem in treatment cases where drug resistance has appeared. It is important, therefore, to establish a plan of management that integrates the need for surgery in the overall medical program, particularly in relation to proper timing.

Combined drug regimens utilizing the three best chemotherapeutic agents in one combination is isoniazid (SM), INH, PAS, or SM INH PAS) have been superior to the administration of single antimicrobial agents and their dosage and method of utilization has been well documented in the literature.<sup>1,2,3</sup> At least one of the most potent agents, streptomycin sulfate or isoniazid, should be reserved for use in the event that a resistant organism or reinfection develops. In general, patients undergoing home care are best treated with the INH PAS regimen. Streptomycin sulfate is usually more conveniently employed for those patients who are undergoing hospital care. When prolonged treatment with SM is anticipated for patients having extensive disease in whom the outcome is very much in doubt (e.g., bilateral cavitory disease), it is desirable to combine SM with PAS (to conserve INH) unless PAS intolerance makes its combination with INH necessary. The experienced chest physician will recognize pulmonary lesions which may be expected to respond favorably in from 1 to 2 years to a well integrated therapeutic program, and it makes little difference what combination of drugs (SM, INH, and PAS) are utilized in such patients. These include, for example, patients with minimal pulmonary lesions, uncomplicated pleural effusion, recent noncavitory lesions of moderate extent which are presumed to be predominantly reversible by their diffuse or ill defined characteristics in the chest roentgenograms,

TABLE 2 Integrated drug and surgical treatment of pulmonary tuberculosis based on an estimate of the lesion

Classification of lesions	Medical treatment	Surgical treatment
Undertreated	Standard therapy directed by clinical signs and response as revealed by bacteriologic and roentgenologic studies	Specific drug prophylaxis and/or thoracoplasty
Reversible	Reversible lesions remediable by medical means. Use of drugs and surgery until the irreversible stage of disease. Operative procedure required.	
Irreversible	Irreversible lesions remediable by medical means. Use of drugs and surgery until the irreversible stage of disease. Operative procedure required.	
Reversible	Reversible lesions remediable by medical means. Use of drugs and surgery until the irreversible stage of disease. Operative procedure required.	
Acute	Acute lesions remediable by medical means. Use of drugs and surgery until the irreversible stage of disease. Operative procedure required.	
Chronic	Chronic lesions remediable by medical means. Use of drugs and surgery until the irreversible stage of disease. Operative procedure required.	

After 6 to 12 months of drug therapy, if the response is not satisfactory, surgical intervention is indicated. (See table of resectional components below)

TABLE 2 Integrated drug and surgical treatment of pulmonary tuberculosis based on an estimate of the lesion-class

Classification of lesions	Medical treatment	Surgical treatment
Reversible and irreversible —Cont'd— Chronic fibrocystic epithelioma (adenomatous and intracystic lesions)	Specific drugs Temporary collapse	Excision of the lesion Resection of the breast
Mixed lesions with a reversible exuberant component Irreversible fibrocystic component	Reversible lesions: tamoxifen, endocrine therapy Exuberant lesions: tamoxifen, endocrine therapy Irreversible lesions: tamoxifen, endocrine therapy	Excision of the lesion Resection of the breast

and finally the more serious necrotic lesions with or without cavitation so well localized that definitive surgical treatment may be considered after 6 to 12 months of drug therapy. At the present time there appears to be no need to combine all three of our commonly used drugs (SM, INH and PAS) in the routine treatment of pulmonary tuberculosis. Complications of miliar or meningeal disease or seriously ill patients with acute caseous pneumonic tuberculosis are exceptions to this generalization.

It has been fairly well established that prolonged uninterrupted drug treatment produces the most lasting treatment results. Follow up studies at this hospital have revealed a high relapse rate in patients treated in the prechemotherapy era. This was greatly reduced by the utilization of short drug regimens (from 2 to 6 months) but following the adoption of long term chemotherapy in 1951 with treatment continued to the stage of inactive disease less than 5 per cent of the patients have had relapses (table 3). From these studies it is reasonable to conclude that drug therapy should be used for patients undergoing definitive treatment until the lesion has been well stabilized for a prolonged period. The therapeutic target point of "inactive disease" as defined by the National Tuberculosis Association means that the patient has no symptoms due to tuberculosis, the sputum is negative and the roentgenograms of the chest reveal a stable noncavitary lesion for at least six months. If this stage of recovery is reached in less than 12 months drug therapy should be continued for a minimum of one year. After surgical procedures particularly resection for lesions revealing active disease in the resected lung specimens, drugs should be continued no less than from 6 to 12 months after the operation.

There have been no new developments in the field of operative procedures for pulmonary tuberculosis except for the virtual abandonment of pneumothoraxy, decreased use of thoracoplasty and the extended use of pulmonary resection. Of the temporary collapse procedures so important a few years ago only pneumoperitoneum has carried over into the current chemotherapy era. Its value is perhaps limited to the treatment of cavitory disease used early in the course of treatment<sup>10</sup> but the operation is used infrequently today. Primary thoracoplasty is seldom employed but it may be useful for cavitory disease of the upper lobes when disease elsewhere is too extensive to consider resection. The removal of localized pulmonary lesions has been made possible by prolonged chemotherapy and proportionately more wedge and segmental resections are now possible. These trends are well illustrated by the statistics of chest surgical procedures utilized at this hospital during 1947-1955 (table 4).

One new chemotherapeutic agent, cycloserine, has been introduced recently under the proprietary names Seromycin and Oxa

TABLE 3 Distribution of temporary retired cases reviewed at 1st January 1957 to 1 January 1957

pyrazinamide<sup>10-11</sup> This antibiotic is undergoing clinical investigations at present and is not available for general use. Preliminary reports indicate that the drug alone is less effective than other combined regimens, however, in combination with INH it may prove effective. At dosages of 1 gram daily, or higher, convulsions will occur in about 5 per cent of patients. None have been reported with dosages of 0.5 gram daily. The role of Pyrazinamide

mide (brand of pyrazinoic acid amide)<sup>12-17</sup> has not been clearly defined in spite of extensive study in the past few years. Its best application appears to be in combination with INH but its hepatotoxic effect limits its use and it has not been made generally available.<sup>10, 12, 17</sup>

### DISCUSSION

The improvements that have been made in the management of pulmonary tuberculosis in the past five years have greatly increased the patient's chances for recovery. Furthermore, statistical studies made on the health of patients who have recovered from this disease during the era of prolonged chemotherapy show that most patients treated to the stage of inactive disease remain well (table 3).

There are a considerable number of patients who cannot be treated successfully because of inoperable, active, far advanced disease. There is presently no solution for these problems and because of the factor of contagion, rehabilitation of the patient to a useful place in society becomes difficult even though his general health remains good. Hope for partial rehabilitation for this group of so-called "good chronics" lies in the possible total eradication of *Mycobacterium tuberculosis* from the body by some effective drug combination not yet discovered, thus removing the public health hazard. Conversion of the sputum to negative with the continuous use of agents now available is helpful in this

group of patients, but experience is lacking on how many years these drugs will keep the sputum negative

Still another group of individuals who are greatly improved by chemotherapy do not fully recover because of persistent cavity residuals and the unavailability of effective surgical treatment. This group offers a great challenge for the future. Since all operable patients with persistent cavity tuberculosis require surgical treatment, the training of more thoracic surgeons is a matter of great urgency in most countries.

Pulmonary tuberculosis in patients who have received drug therapy has been a subject of much interest in recent years. In spite of intense investigation, one of the most controversial problems has been the method of choice of treating necrotic foci of varied size and extent which remain after prolonged courses of chemotherapy. Many of these patients without persistent cavitation recover and remain well, but the threat of relapse under physical stress and the prolonged physical restriction required to assure continued good health makes this problem of more than academic interest. It is known that present day antimicrobials do not sterilize the necrotic lesion and *Mycobacterium tuberculosis* persist in many of these areas. Furthermore, healing of the unsloughed necrotic focus is by the slow process of fibrous encapsulation and gradual drying out of the contents which may require many years.

The sloughing of the necrotic lesion results in cavitation which must terminate in one of the following ways. First of all, it may slough completely and close cleanly, leaving only a small scar of no clinical importance. The opening of the cavity may close and constitute the so-called blocked cavity or tuberculoma with its accumulated caseous and necrotic tissue. These lesions are potentially dangerous because it is unusual for them to absorb and difficult for them to organize or to slough completely so that viable *Mycobacterium tuberculosis* can persist in them for long periods and eventually be disseminated. Mitchell has shown a 25 per cent clinical relapse in such cases prior to chemotherapy.<sup>18</sup> Studies at this hospital revealed from drug assays of resected tuberculomas that streptomycin sulfate does not penetrate the fibrous walls and viable bacilli are frequently present.<sup>19</sup> Another result that follows sloughing of necrotic lesions may be the maturation of so-called open cavity healing in which epithelialization of the bronchocavitary junction prevents complete closure by interfering with the approximation of the opposing granulation tissue surfaces. It is rare that such a lesion exists as an innocuous focus. More often than not, caseous areas remain in or near the cyst-like cavity wall and hence such lesions must always be presumed dangerous. Finally, the sloughing of the caseous lesion may result in an open cavity with necrotic walls containing

numerous viable *Mycobacterium tuberculosis*—the most dangerous of all lesions as far as contagion and spread of infection is concerned

The question of how to treat the patient with negative sputum and who has small residual noncavitary, necrotic foci has not been completely answered but the trend is toward conservative treatment. The solution to this problem is a difficult one because diagnostic methods are not exacting enough to differentiate those lesions which are well encapsulated and stable from those which have great potential for breakdown because of their bronchial communications and lack of fibrous encapsulation. It is known that cavities and foci of active disease that were unsuspected by roentgenographic examination are sometimes found by the surgeon at the operating table. Furthermore one cannot determine preoperatively the bacterial flora of the necrotic focus whether the organisms will be abundant or whether it will be difficult to culture them due to the bacteriostatic effect of the low oxygen tension and presence of organic acids. The real significance of the few organisms that survive in a dormant state has not been determined but it must be presumed that they carry danger of relapse for many years. Studies have been proposed to solve the problem of therapy for those patients by analyzing the results after treating some with resection of the lesion and treating others by prolonged drug therapy. This of course will be limited largely to research centers and until a solution is forthcoming through long term follow up studies one must arbitrarily decide from the present available facts the treatment of choice. Unless there is evidence that the disease is not controlled well by chemotherapy as evidenced by clinical roentgenographic or bacteriologic findings patients with small caseous foci should have drug therapy at the present. The gratifying results from antimicrobial therapy alone and the unavailability of thoracic surgeons to operate on the known cavitary lesions in patients urgently in need of surgery fully justifies this approach at present.

It is recognized that drug therapy and operative procedures are very important in the treatment of the tuberculous patient but it should be remembered that the total rehabilitation of the individual to his rightful place in society requires much more. We are treating an individual and not just a pulmonary lesion. Patients must be carefully supervised until they recover from their disease and then be placed in positions of employment that will give them a reasonable chance of remaining well. The importance of this phase of management is well illustrated by the experiences at this hospital (table 3). Eighty four per cent of 1117 tuberculous patients among military personnel treated in the hospital to the inactive stage of the disease were rehabilitated and declared fit for restoration to duty in the period 1949 to 1956. The relapse rate in this series was only 3.2 per cent and there were no deaths.

January 1957)

due to tuberculosis. This is good statistical evidence that a carefully controlled rehabilitation program is quite worthwhile.

### CONCLUSIONS

The present and treatment of pulmonary tuberculosis permits a very optimistic viewpoint for patients presently undergoing treatment and for continued success in the future. Inasmuch as all studies confirm the fact that those persons found in the initial stages of the disease can almost be assured of recovery and future good health if they co-operate with their physician, the responsibility to discover and treat these patients early is one of our most urgent problems. The success in treatment depends almost entirely on the extent of the chronic necrotic and cavity residuals remaining after 6 to 12 months of specific drug therapy. If these residuals are very extensive, the opportunities for utilizing modern methods of therapy in a definitive manner may be lost.

In the final analysis, each patient with pulmonary tuberculosis must be judged individually, and the choice of his treatment made in relation to the character of the disease, the behavior of host resistance, the character of the chronic residual, and the degree of stress expected in the individual.

### A CONCEPT OF DIABETES

We do not know the cause of diabetes nor do we understand its very real relation to growth and size but apparently diabetes in the latent form (pre-diabetes) remains with the victim years or decades before he or she becomes overtly diabetic. During this time pregnancy, corticotrophin therapy, acquisition of Cushing's syndrome or of acromegaly, a staphylococcal infection or overeating may uncover the individual already predisposed to diabetes. The previously adequately compensating pancreas cannot stand the additional stress completely and evidence of the latent diabetic state is brought to the surface divulging its menacing presence by embryopathies or changes in carbohydrate tolerance. Hence it is wrong to talk of diabetes only when glycosuria and hypercalcaemia are present. It is a disorder which goes back much further than that—even into the womb.

# PLEURISY WITH EFFUSION DUE TO REMOTE TRAUMA

## A Differential Diagnosis for Acute Idiopathic Pleural Effusion

PERRY BERG (Captain USAF (MC))  
EUGENE P. TRIAKEL Captain USAF (MC)  
CHARLES B. SHIVER Jr. Captain USAF (MC)  
TIMOTHY A. CARIS Captain USAF (MC)

PLEURISY with effusion especially when discovered in young people, has long been a difficult and vexing problem to the clinician. In many cases a definitive diagnosis may be made with the roentgenographic and laboratory methods ordinarily available, in a considerable number however, the disease remains "idiopathic" despite careful and complete evaluation.

When patients with the "idiopathic" type have been observed over prolonged periods, it has been established that an appreciable majority eventually develop some signs indicative of tuberculosis.<sup>1-3</sup> In published series, the highest figure for the majority has been placed at 66 per cent,<sup>4</sup> it has been estimated however, that tuberculosis is the cause of as high as 90 per cent of cases of pleurisy with effusion without demonstrable cause.<sup>5</sup> Pathologic studies of pleural adhesions have reinforced this close relation up to the incidence of tuberculosis.<sup>6</sup> From these sources has evolved the clinical dictum that an idiopathic pleural effusion in a young person is tuberculosis unless proved otherwise.<sup>4</sup>

When doubt exists as to the cause of a pleural effusion, accurate diagnosis of the cause by biopsy with a Vim Silverman needle<sup>7</sup> or through direct incision<sup>8</sup> has been advocated as a diagnostic procedure. The two series in which pleural biopsy was done were composed of 45 patients and included a description of the method of pleural biopsy<sup>9</sup> and considerable information as to the pathology of pleurisy with effusion.<sup>8</sup> Both series stressed that only atypical cases warrant this procedure, more conservative diagnostic methods usually suffice. The proportion of nontuberculous to tuberculous pleurisy varied from 4/21 in one series to 2/24 in the other, all in the latter series initially being considered

From U. S. Air Force Hospital APO 994 San Francisco Calif. Dr. Berg is now at 59 Second Ave. New York 3, N. Y.

as probably tuberculous. The method of selection probably accounted for the difference in the above figures. Parenthetically in the second series, three cases were considered as due to tuberculosis because of the finding of acid fast bacilli in sputum or chest fluid, but at surgery no sign of specific infection could be found. In both reports the authors concluded that, in cases where the diagnosis is in doubt, pleural biopsy is a safe and effective tool.

Trauma, long known to be a cause of pleural reaction and effusion, is considered to exert its effect at the time of the traumatic event. Persistent pleural abnormality is considered a result of unresolved hemothorax. No mention can be found in the medical literature of chest wall injury giving rise to pleural reaction with effusion sometime after the traumatic event, though several mechanisms exist that may give rise to this sequence of events.

This report deals with two instances of pleural fibrosis with effusion ascribed to trauma that occurred six months and two years prior to the discovery of the pleural disease. Both were men in their thirties, both were treated in a hospital at the time of the trauma and both sustained rib fractures. One failed to demonstrate initially any signs clinically or radiologically of pleural reaction to the trauma; in the other patient a small amount of pleural fluid, thought to be hemothorax, had been completely absorbed by the time he was discharged at the end of the initial hospitalization. Several interval roentgenograms confirmed the absence of pleural reaction until the effusion appeared. Effusions in both patients developed in the area of maximum injury. Both were considered tuberculous, partially due to the report of acid fast bacilli in the sputum or gastric contents on single specimens. Finally, because of inconsistencies in the clinical pictures of both cases, thoracotomy was performed to resolve the diagnosis and coincidentally serve as a therapeutic maneuver.

### CASE REPORTS

Case 1. A 33 year old man was admitted to this hospital on 8 April 1955 for evaluation of a pleural effusion.

The patient had been perfectly well prior to 19 March 1952 (several routine roentgenograms being reported as negative) when he was severely injured in an automobile accident. His injuries included multiple fractures of the first five anterior ribs on the right as well as the sternum. A roentgenogram on the day of injury revealed only the rib fractures, but subsequently a pleural reaction was noted on the right as well as an atelectatic area in the right upper mid lung field. A roentgenogram 19 days later was similar, but by 2 June the reaction was much smaller. Films taken in September 1952 showed complete disappearance of these findings (fig. 1).

Figure 1 (case 1) Roentgenogram of the right side of the chest taken in September 1952. The healed fractures of the anterior portions of the right ribs may be seen. No pleural reaction is present. Figure 2 (case 1). Roentgenogram taken in October 1953. The patient complained of a cough. The density seen at the cardiophrenic angle was considered to be a patch of pneumonia.

In October 1953 he complained of a chronic cough and a roentgenogram taken at that time revealed an infiltrate along the right cardiac border (fig 2) He was treated with chlortetracycline hydrochloride (aureomycin) and the area was clear on subsequent films (fig 3)

In January 1955 he complained of wheezing Roentgenographic findings at this time were normal except for the healed rib fractures (fig 4) In February pain of a pleuritic type appeared in the right side of the chest A roentgenogram at this time showed reappearance of the paracardiac density on the right side and slight clouding of the costophrenic sulcus (fig 5) He was thought to have pneumonia but in April 1955 roentgenograms revealed blunting of the costophrenic angle (not seen in the previous film) and an area of discoid atelectasis in the right lower lobe (fig 6) At this time he was admitted to this hospital

Physical examination revealed only dullness to percussion and a few scattered crepitant rales over the lower right side of the chest posteriorly The temperature never exceeded 99.4°F and usually was normal

Complete blood cell counts were within normal limits The corrected sedimentation rate ranged from 25 to 32 mm/hr Cold agglutinin titers on at least six occasions were normal

Bronchoscopy revealed inflammation of both middle and lower lobe bronchi A biopsy of this area revealed only chronic inflammation A tuberculin skin test using first strength PPD was read as questionable and one using second strength PPD was strongly positive A thoracentesis yielded 65 ml of blood-tinged fluid A smear of this fluid was negative for tumor cells and acid fast bacteria the fluid was sterile for acid fast and pyogenic bacteria on culture Several sputum blood and urine cultures were negative for pathogens cultures of sputum for fungi were negative Eight sputum smears and cultures were obtained and were negative for acid fast bacteria however on 26 April acid fast bacteria were identified in a sputum smear and after seven days culture on blood media acid fast bacilli were noted This culture eventually proved to be a chromogenic organism nonpathogenic for the guinea pig On 27 April a gastric smear revealed acid fast bacilli These did not grow on culture media other gastric smears and cultures were negative

Serial roentgenograms revealed only minor changes in fluid level and a small pneumothorax after thoracentesis (fig 7) Clouding of the costophrenic sulcus on the right side was seen inconstantly on several films Fluoroscopy revealed pulsation in that area as well as restriction of the diaphragmatic excursion on the right A course of antibiotics failed to alter the roentgenographic picture because of the possibility of neoplasia he was referred to Fitzsimons Army Hospital for further study

Additional preoperative studies there revealed a vital capacity of 3.4 liters (78 per cent of the predicted value) Sedimentation rate was

4

Figure 3 (case 1) Roentgenogram taken one month after figure 2. The density previously noted in the costophrenic sulcus is no longer visible. Figure 4 (case 1) Roentgenogram taken in January 1955. At this time the patient complained of some shortness of breath. Both costophrenic and cardiophrenic angles are normal.

Figure 5 (Case 1) Roentgenogram taken seven weeks after figure 4. The patient complained of pleuritic pain in the right side of the chest. There is some clouding of the costophrenic sulcus and a more definite cloudiness in the cardiophrenic angle. Figure 6 (Case 1) The roentgenogram taken one month later than figure 5 shows considerable fluid in the costophrenic angle and an increase in the paracardiac density. The linear density of the fluid level was interpreted as an area of discoid atelectasis.

7

8

Figure 7 (case 1). Appearance of the right side of the chest in July 1933 approximately two weeks prior to thoracotomy. The pleural fluid in the costophrenic sulcus has resorbed although the paracardiac density persists. The area previously considered atelectatic has increased somewhat at exploration it proved to be pleural thickening Figure 8 (case 1). Bronchogram taken in the left oblique projection showing filling of the right middle lobe and illustrating the well filled but compressed bronchi that led to a preoperative diagnosis of "capture" of the right middle and lower lobes by pleural thickening.

11 mm/hr. Three gastric aspirations were negative for acid fast bacilli on smear and culture. Reaction to a tuberculin skin test using first strength PPD was positive. Skin tests for coccidioidomycosis and histoplasmosis were negative. Bronchoscopic examination revealed a small mucosal-covered 0.5-cm lesion in the region of the lateral wall of the right middle lobe bronchus obstructing about 10 to 15 per cent of the bronchial lumen. Biopsy of this area revealed only chronically inflamed bronchial tissue. Bronchial washings were negative on culture for acid fast bacilli.

Laminagrams confirmed the thickening of the pleura over the right middle and lower lobes. The right middle lobe was partially atelectatic as was the anterior basilar segment of the right lower lobe. A bronchogram revealed the right middle lobe bronchus to be closer together than normal but well filled. The basilar segments of the right lower lobe bronchus were only partially filled and some irregularity of the bronchial walls was noted (fig. 8). These results indicated that there was "capture" of the lower and middle lobe by thickened pleura. Treatment with penicillin and streptomycin sulfate was begun and a thoracotomy was performed.

The visceral and parietal pleura were adherent over the diaphragm, mediastinum and pericardium. The thickest part in the vicinity of the major fissure posteriorly and laterally was 1 to 2 mm thick firm and fibrous and was entrapping the middle and lower lobes. Over the pericardium a mass of fat was encountered adherent to the pericardium and diaphragm by thin fibrous adhesions. This was identified as omentum and was completely separated. Palpation in the vicinity of the foramen of Morgagni revealed a firm fibrous plug of omentum but no real defect in the diaphragm. About 95 mg of pleural peel was removed.

On microscopic examination it was noted that sections of the pleural peel contained fibrous connective tissue and a prominent chronic inflammatory reaction consisting of lymphocytes and plasma cells. Several scattered granulomatous lesions containing multinucleated giant cells were seen. Neither caseation nor acid fast bacilli were found in any portion of the specimens. The final pathologic diagnosis was non specific pleuritis.

The postoperative course was uneventful. A postoperative roentgenogram revealed some fluid at the right base which was gradually absorbed. The right costophrenic angle remained obliterated. The patient was discharged without further therapy to full duty. Six months later he was still active and completely asymptomatic.

**Case 2.** A 35 year-old man was admitted to this hospital for the second time on 3 September 1955 for evaluation of a pleural effusion.

In December 1954 the patient fell from a considerable height fracturing several left posterior ribs. He was admitted to the hospital complaining of severe pleuritic pain in the left side of his chest and fever.

Roentgenograms, however, revealed no pleural or pulmonary lesions and he was discharged asymptomatic after nine days of rest and antibiotic therapy (fig 9). He was completely asymptomatic thereafter. In July, he reported for an annual physical examination. Both physical and radiologic evidence of left pleural fibrosis and effusion were noted (fig 10) and after preliminary outpatient study he was admitted to the hospital. The blood cell count was within normal limits and a urinalysis, serologic test for syphilis and skin tests for tuberculosis, coccidioidomycosis and histoplasmosis were negative. Thoracentesis on the fourth hospital day produced only 10 ml of clear yellow fluid containing 1,100 lymphocytes per  $\mu$ l and 3.99 grams of protein per 100 ml. The fluid was sterile. A second thoracentesis 12 days later produced 100 ml of a similar fluid. In both cases, loculation of the fluid was believed to be present. The sedimentation rate varied from 17 to 33 mm per hr. Several sputa and gastric analyses were negative for acid fast bacteria by smear and culture. However, one sputum specimen, obtained six days before operation, contained acid fast bacteria on smear and culture. A guinea pig inoculated from this sputum survived. Autopsy failed to reveal evidence of tuberculosis.

Roentgenograms revealed minor variations in the extent of the effusion (fig 11). At no time was a parenchymal lesion seen. Films made with the patient in decubitus and upright positions were almost identical, suggesting that most of the density represented pleural fibrosis rather than effusion. At fluoroscopy, the left diaphragm was somewhat limited in excursion. Roentgenograms of the gastro-intestinal tract, skeleton and kidneys were normal.

The patient was completely asymptomatic and afebrile all through the period of investigation, during part of which he was returned to limited duty. A total of seven skin tests for tuberculosis utilizing second strength PPD were performed, all were negative. He gained approximately 12 pounds while in the hospital. Biopsy of the pleura with a Vim-Silverman needle was attempted; the specimen contained only skeletal muscle and fibrous tissue. The fibrous tissue was infiltrated with lymphocytes arranged perivascularly but was not identifiable as pleura.

Thoracotomy revealed a thickened pleura over the left lower lobe without obliteration of the pleural space. The lung was normal to palpation. Approximately 60 ml of thin clear fluid was present. Surgical decortication was performed. Microscopic examination of the peel revealed only fibrous tissue with some minor inflammatory reaction (fig 12). The pleural fluid was sterile on culture for acid fast bacilli. The postoperative course was uneventful; the patient returned to full duty within 45 days and was completely well 1 year later. He engages in relatively strenuous physical labor.

#### COMMENTS

It is not suggested that this report in any way controverts the current concept that tuberculosis is the cause in almost all

Figure 9 (case 2) Roentgenogram of the chest taken immediately after the patient had fallen and fractured the left ribs and tenth ribs posteriorly (hidden by the diaphragmatic shadow). The costophrenic angle was normal. Figure 10 (case 2) Roentgenogram taken approximately six months after figure 9. There is now a left pleural effusion with pleural thickening.

idiopathic pleural effusions. However, pleural effusions complicate many diseases.<sup>3, 10, 11</sup> Occasional cases of pleurisy with effusion are seen, due to various causes, which either cannot be diagnosed by the usual means or are confused by false positive bacteriologic information. In the series of Stend, Eichenholz, and Stauss,<sup>8</sup> chronically active organizing pneumonia, prior spontaneous pneumothorax or hemopneumothorax, and histoplasmosis were the basis of effusions. Their experience with false positive bacteriologic tests for acid fast bacilli has previously been mentioned.

*Figure 11 (case 2) Roentgenogram taken a few weeks before operation. The pleural effusion has decreased slightly. No parenchymal lesion is seen.*

We believe that prior trauma to the chest wall should be added to the list of causes of pleurisy with effusion. Neither remoteness of the trauma in terms of months to a few years, nor absence of pleural reaction at the time of injury eliminate trauma as a cause of the lesion. While it is difficult to draw conclusions from only two cases, some clinical support may be obtained for the diagnosis when a history of trauma is obtained. Our experience re-emphasizes the value of the tuberculin skin test.<sup>3</sup> Tuberculous pleurisy with effusion is thought to be a consequence of either

rupture into the pleural cavity or contiguous inflammation. In the tuberculin sensitive person the pleural reaction leads to a considerable exudation of fluid and dilution of organisms to a point where smears and cultures will appear sterile. Absence of tuberculous sensitivity, evidenced by negative skin reactions, would make this sequence unlikely. Where the problem has been investigated conversion of the skin reaction from negative to positive has preceded the appearance of pleural effusion by six months.<sup>12 13</sup>

Figure 12. Section of pleural peel removed at thoracotomy. It consists almost entirely of fibrous tissue with but a minor inflammatory component ( $\times 130$ ).

The presence of a relatively small effusion and a considerable degree of fibrosis especially early in the course of the disease demonstrated clinically by only small amounts of fluid available at thoracentesis and only minor changes in configuration in roentgenograms made with the patient in decubitus position also suggests a nontuberculous cause. Stead, Eichenholz and Stauss suggested laminagraphy as a means of demonstrating subpleural nodules; the absence of these may be added to other evidence in making a clinical diagnosis. Study of the pleural fluid sugar or beta glucuronidase levels have also been mentioned as of diagnostic value.<sup>14 15</sup> Finally where doubt exists the pleural biopsy would seem preferable to empirically treating the patient for tuberculosis. This procedure can be performed through a small incision without most of the sequelae of major chest surgery.<sup>9</sup> Pleural

biopsy with a Vim Silvermann needle,<sup>7</sup> attempted in case 2, did not result in adequate tissue for a diagnosis.

The mechanism of the late development of pleural fibrosis and effusion after trauma is speculative but some comments can be made. In case 1 the presence of herniated omentum probably acted as a stimulus for continued pleural reaction. In addition, pleural fluid had been present in this area shortly after the initial trauma but was completely absorbed during convalescence. The pleural peel was thickest over the major fissure, posteriorly and laterally, and presented the histological picture of a foreign body reaction. In case 2, no herniation was present, pleural laceration or hemothorax may have appeared following discharge from the hospital. The complete absence of any symptoms during this period makes this unlikely; however, it is more likely in both cases that radiologically invisible pleural inflammation remained after the acute traumatic phase apparently subsided. This inflammation may have excited further fibrosis. Continued fibrosis after inflammation analogous to keloid formation has been postulated as being the cause of masses of fibrous tissue in the pleura that have been labeled "pseudotumors."<sup>8</sup> Although this sequence usually follows an infectious disease, a similar pattern may occur with trauma and rib pleural injury.

Once a considerable degree of fibrosis is present, fluid formation is explainable. Stead and his group encountered seven instances of what they referred to as "trapped lung" in a group of nine patients with nontuberculous pleurisy with effusion who were subjected to thoracotomy. They found that the lower portion of the lung was encased and compressed by a thin, tough fibrous peel. There was no pleural symphysis. The upper lobe, also covered by thickened pleura, could not fill the space left by the compressed lower lobe. As a consequence, fluid was drawn into the pleural space to restore normal pressure relationships. In case 2, a mechanism similar to this certainly existed. Both pleurae were thickened although there was no obliteration of the pleural space. In case 1 lung trapping was suggested preoperatively by the compression of the bronchi as seen on bronchogram. Further, at exploration the surgeon noted that the fibrous peel entrapped the middle and lower lobes to a significant degree. Despite removal of 65 ml of fluid by thoracentesis four months before, the pleurae were adherent, and no fluid was reported at operation. Apparently, continuation of the fibrosing process obliterated the necessary space.

Finally, it is interesting to mention briefly our experience with the reports of positive smears and cultures for acid fast bacilli. In one case a simple chromogenic organism was involved. Case 2 is much more complex. Here a single smear and culture were positive. Although a guinea pig inoculated with a concentrate of the

material survived without change in reaction to the skin test, another animal inoculated with the organism obtained from the culture died and autopsy revealed typical tuberculous lesions. Further study however revealed that the organism was resistant to streptomycin sulfate, para aminosalicylic acid and isoniazid, although the patient in question had received no therapy at that time. At the same time, the laboratory was processing a culture slant obtained from another patient previously treated and containing an organism with identical cultural reactions and sensitivities. In view of the persistently negative tuberculin test the absence of parenchymal disease to palpation and inspection at thoracotomy and the nonspecific histological picture of the pleura cross contamination in the laboratory seems likely. The experience of others with reports of acid fast bacilli in body fluids later contradicted by the operative findings has been alluded to previously. The opportunity for error is present in a situation like that of most small military hospitals where relatively untrained personnel collect and label specimens and where such specimens must be shipped to a laboratory receiving and processing collections from many different areas. In addition cross contamination is a possibility in the laboratory itself. The bacteriologic finding then must be carefully evaluated in the light of the clinical picture and associated tests. Where these are contradictory the possibility of incorrect bacteriologic information must be considered.

#### SUMMARY

Tuberculosis is undoubtedly the cause of the vast majority of "idiopathic" pleural effusions. However severe chest wall trauma may be a cause of some of the remainder. When a history of such an injury is obtained the clinical and laboratory data must be especially carefully scrutinized for evidence of nontuberculous cause of the effusion. Where doubt exists resolution of the dilemma by pleural biopsy would appear to be preferred to an empirical therapeutic regimen for tuberculosis.

In two patients with pleural effusion following trauma by months to years partially because of false positive bacteriologic reports and in part because of normal interval roentgenograms tuberculosis was considered the diagnosis of choice. Contradictory findings led to exploration of the chest with examination of the lung pleural biopsy and finally decortication. In both no evidence of tuberculosis was found and the fibrosis and effusions were ascribed to the trauma. The mechanism of delayed post traumatic pleural effusion is unknown but it is likely that radiologically invisible pleural inflammation remains after the acute traumatic phase subsides. This inflammation may produce increasing pleural fibrosis which compresses encases and traps the lung. As a consequence fluid is drawn into the pleural space to restore normal pressure relationships.

# A PANORAMIC X-RAY DENTAL MACHINE

DONALD C. HUDSON *Colonel USAF (DC)*

JOHN F. KUMPULA

GEORGE DICKSON *MA*

**T**HE NEED for a simple and rapid method of recording dental conditions of large numbers of people has existed in the armed services for some time. Such records are particularly desired on persons entering the services to provide evidence of the general dental health level of the subject and information on dental treatment requirements during the service life of the individual and to aid in establishing identification records.

Present methods in which intraoral films are used require the placement and exposure of 14 or more films. This creates a time-consuming problem in processing and handling and fails to show pathologic conditions lying outside the field covered by the small films.

Several methods for producing full mouth dental x rays on a single film both intraorally and extraorally have been explored. Smathers,<sup>1</sup> Nelsen and Kumpula,<sup>2</sup> Zulauf,<sup>3</sup> Paatero,<sup>4</sup> and Blackman<sup>5</sup> have produced such radiograms using machines of various designs.

Development of a dental x ray machine designed to produce full mouth radiograms on single 5 by 10 inch films was undertaken at the National Bureau of Standards Dental Research Laboratory. The program has been carried on in co-operation with the U. S. Air Force Dental Service and the U. S. Air Force School of Aviation Medicine.

An extraoral method termed curved surface laminagraphy was selected for the present development because of the simplicity of the technic and the fact that fitting and placement of a bulky lead backed film in the patient's mouth would not be required. It was also decided that rotation of the x ray source and film holder would be employed rather than rotation of the patient and chair as described by Paatero,<sup>4</sup> thus further simplifying the apparatus.

---

From Dental Research Section, National Bureau of Standards, Washington, D. C.   
Walter C. Hudson was Guest Worker Mr. Kumpula, Laboratory Mechanical Division,   
Office of Physical Research.

Colonel Hudson now at School of Aviation Medicine, Randolph Air Force   
Base, Texas.

## METHOD

The principles of curved surface radiography have been discussed by Pantero<sup>1</sup> and by Duhamel.<sup>2</sup> The essential condition for this type of radiography is that the shadow or image of the object that passes through a beam of x rays must fall on a film that is moving at the same velocity as is the image. Pantero has shown that the synchronization of image and film in dental radiography can be obtained by rotating in opposite directions the subject and a film curved to the shape of the dental arch. In the panoramic machine described in this report, synchronization of image and film is obtained by moving a flat film by means of a cable passing around a cam shaped to simulate the curve of the dental arch.

The present form of the panoramic machine was adopted after preliminary studies were made to determine geometric relationships and factors influencing projection of images of the dental mouth structures. In one device, a light beam was employed rather than x rays, and transparent plastic models of the dental arches containing opaquely outlined tooth silhouettes were used. Photographic printing paper was substituted for film. Information gained in the above experiment was applied to the design of another panoramic device using an x ray source and a human skull. This model did not provide for movement of the x ray source due to the bulk and weight of the x ray tube head. The subject (skull) was rotated and the film holding device rotated to achieve the same geometric pattern as had been obtained in the light beam model. Many radiograms were made with this device, using different x ray exposures, different rates of motion, different positions of subject, film, and x ray source, and various widths of x ray beam. Information gained was used in the design of the machine that represents the final development achieved in this project to date.

In the final form of the machine, shown schematically in figure 1 and photographically in figure 2, the x ray source and film holder are rotated around the subject so that the axis of rotation  $R$ , is just medial to the angle of the mandible on the side opposite to that to be radiographed. The rate of linear motion of the x ray beam as it sweeps the dental arch varies with the changes in curvature of this arch. Molar and bicuspid teeth, for example lie on the circumference of a circle whose radius,  $r_1$ , is slightly shorter than that of a circle whose circumference passes through the incisor and cuspid teeth, the center of both circles being located at the center of rotation previously described. Therefore the linear rate of motion of the film past the vertical slit,  $U_1$ , in the face of the film holder must be slightly increased when projecting the anterior teeth as compared to the linear rate when projecting the posterior teeth. This variable rate is provided by the cam of the film drive mechanism.

Figure 1 Schematic diagram of panoramic x ray machine

Figure 2 Panoramic x-ray machine

Curvature of an average dental arch is simulated in each of the four lobes of the cam, and its contour is proportioned so that the proper rate of movement of the film past the film housing vertical slit is maintained by the endless cable which passes around the cam and is attached to the film cassette. The result is a projection of those dental structures lying on the curved surface described by the dental arch, while structures lying outside or inside this surface are projected in such distorted and diffuse shadows that they do not interfere with the visualization of the structures to be radiographed. Since the divergence of the x ray beam produces a slight magnification in the image, the over all rate of the film movement dictated by the size of the cam must be slightly greater than the rate of linear motion of the x ray beam along the line of the dental arch.

The method by which the panoramic image is obtained is shown schematically in figure 1. The diagram shows the arrangement for exposing one half of the arch. After this half is exposed, the subject is moved laterally so that the axis of rotation is back of the molars on the opposite side of the arch, the source and film holder are repositioned, and the second half of the arch is then exposed. In practice the subject and cam remain in a fixed position during the exposure while the source and film holder are rotated around them. In principle this is identical to holding the source and film holder fixed and rotating the subject as shown in figure 1. From this figure it can be seen that a clear image of T can be obtained only if the film moves so that at all times point I is on the extension of a straight line from the source S through T as T moves through the x ray beam (from T<sub>1</sub> to T<sub>2</sub> to T<sub>3</sub>). This condition will be met if

$$\frac{FI}{SI} = \frac{r_T \sin \phi}{SR + r_T \cos \phi} \quad 1$$

where  $\phi$  is equal to or less than  $90^\circ$ . Since  $\phi$  is small it can be assumed that  $\cos \phi = 1$  and  $\sin \phi = \phi$ . Equation 1 therefore can be written

$$\frac{FI}{SI} = \frac{r_T \phi}{SR + r_T} \quad 2$$

Using this relation, the dimensions of the cam required to control the movement of the film can be determined. The angular velocity  $\omega$  of a point T moving through the x ray beam from T<sub>1</sub> to T<sub>2</sub> in time t is  $\omega = \frac{\phi}{t}$  3

and the linear velocity is

$$\omega r_T = \frac{r_T \phi}{t} \quad 4$$

Assuming that the linear velocity  $V_I$  of the image across the slit is constant, from equation 2

$$V_I = \frac{FI}{t} = \frac{SF r_T \phi}{(SR + r_T)t} \quad 5$$

Substituting from equation 3

$$V_I = \frac{SF \omega r_T}{SR + r_T} \quad 6$$

If the velocity  $V_F$  of the film is controlled by a cable around a cam also moving with angular velocity  $\omega$  the linear velocity of the film is  $V_F = \omega r_C$  where  $r_C$  is the effective radius of the cam when  $T$  is passing through the x-ray beam

For image formation  $V_F = V_I$  or

$$\omega r_C = \frac{SF}{SR + r_T} \omega r_T \quad 7$$

$$r_C = \frac{SF}{SR + r_T} r_T \quad 8$$

This equation gives the required effective radius  $r_C$  at any point on the cam to provide a sharp image of any point  $T$  on the subject at a distance  $r_T$  from the axis of rotation. In the design of the actual cam the geometry of the machine and of the cam, which affects the point of contact of the cable and the cam must also be taken into account.

A point,  $T_\delta$  at a distance  $r_T + \delta$  from the axis of rotation will project a line rather than a point on the film as it passes through the x-ray beam. The length,  $\Delta$  of this line which determines the sharpness of the image can be calculated by comparing the relative positions of the film and image when the image of point  $T_\delta$  is at  $F$  and when the image of this point is at the edge of the slit.

When the image,  $I_\delta$  of point  $T_\delta$  is at the edge of the slit

$$\frac{(r_T + \delta) \sin \phi}{SR + (r_T + \delta) \cos \phi} = \tan \alpha \quad 9$$

Considering  $\cos \phi = 1$  and  $\sin \phi = \epsilon$  since  $\phi$  is small

$$\epsilon = \frac{(SR + r_T + \delta) \tan \alpha}{r_T + \delta} \quad 10$$

The distance  $l l_\delta$  when  $l_\delta$  is at the edge of the slit, can be written

$$l l_\delta = S l \tan \alpha \quad 11$$

Since  $l_\delta$  and  $l$  will both fall on  $l$  when  $\epsilon = 0$  and since the movement of the film is synchronized with the movement of  $l$  the length  $\Delta$  of the projection of  $l_\delta$  on the film is equal to the distance between  $l_\delta$  and  $l$  when  $l_\delta$  is at the edge of the slit from equation 2

$$F l = \frac{S l r_T \epsilon}{SR + r_T} \quad 12$$

Substituting from equation 10

$$l l = \frac{S l r_T (SR + r_T + \delta) \tan \alpha}{(SR + r_T)(r_T + \delta)}$$

$$\Delta = F l_\delta - F l =$$

$$\frac{S l \tan \alpha (SR + r_T)(r_T + \delta) - S l r_T (SR + r_T + \delta) \tan \alpha}{(SR + r_T)(r_T + \delta)}$$

$$\Delta = \frac{S l SR \delta \tan \alpha}{(SR + r_T)(r_T + \delta)} \quad 13$$

From this equation it can be seen that the sharpness of an image at a distance  $\delta$  from  $r_T$  is proportional to  $S l \tan \alpha$ , which is one half the slit width. Thus, the importance of the slit width in determining the sharpness of the image is apparent. The slit must be narrow enough to provide sharp images of the structures of the dental arch and at the same time must be wide enough so that the shadows of structures not on the dental arch will be blurred to such an extent that they do not interfere with the desired images.

The length on the film of the image of a point at a distance  $r_T + \delta$  from the center of rotation can be calculated by substituting numerical values in equation 13. The approximate values for the present panoramic x ray machine are as follows

SF	425 mm
SR	298 mm
RF	127 mm
$r_T$	50 60 mm
FE	3 75 mm
$\tan \alpha$	0 00882

Substituting in equation 13 and assuming  $r_T = 55$  mm values for  $\Delta$  can be determined. Since the equation gives the value for image movement from the center to the edge of the slit, the total length of the image is equal to  $2 \Delta$ . Calculated values are given below

$\delta$	$2 \Delta$
1 mm	0 11 mm
5 mm	0 53 mm
10 mm	0 97 mm
-10 mm	-1 41 mm

### PROTOTYPE MACHINE

**Construction** As now constituted, the panoramic dental x ray machine is shown in figure 2. A Fischer Model AN<sup>1</sup> bedside radiographic machine base controls and self contained tube head transformer combination were incorporated in the new device. The x ray source and film holding mechanism are suspended from a movable arm which pivots about an axis secured to a large fixed horizontal support arm extending out from the main support column.

A reversible motor with reduction gearing is coupled through a magnetic clutch to a pulley and belt system to drive the movable arm about the support axis. Movement is controlled by mechanical stops permitting about  $200^\circ$  of total rotation, and a reversing switch automatic stop device which automatically stops the machine at the end of one half arch exposure and reverses polarity to the motor as the machine is moved by hand to the opposite side for the second half arch exposure.

Immediately below the axis of rotation is a four lobed cam which with its cable drive moves the film inside the holder at the proper rate to secure exposure of the desired structures.

Regular medical x ray film is placed in a cassette with intensifying screens and inserted into the film carriage in the film holding element of the machine. The carriage is constructed to roll on a horizontal track inside the film holder so that the entire

film can pass a vertical slit in the center of the top face of the film holder housing. This face which is toward the x-ray source is lined with lead and only those x-rays passing through the vertical slit can reach the moving film. Exposure of the entire radiation is reduced in this manner.

X-rays emerging from the source carried at the end of the movable arm opposite the film holder are confined by a vertical lead slit so that a narrow vertical beam is projected. This beam passes directly through the subject and falls on the opposite face of the film holder. Objects in the beam cast sharp shadows on the film in proportion to their relative size as they are as is the case in all x-ray exposures.

**Operation** The subject is seated and his head is positioned by means of a chin rest so that the axis of rotation of the machine falls at a point just medial to the angle of the mandible on the side opposite that to be radiographed. The head is tilted slightly forward so that basal skull shadows will not fall in the area of the teeth but will be projected higher on the film where they will not obscure detail in the dental structures.

The movable arm is swung to the extreme limit of its travel so that the film holder is now near the teeth and jaws of the side to be radiographed. The machine is energized and the x-ray beam sweeps about the rear of the head, from about the posterior border of the ramus of the mandible on the side opposite that being radiographed to a point just lateral to the vertebrae of the neck. At the same time the film holder has moved from its position at the start of the exposure, near the molar tooth region, to a position near the incisor teeth of the side of the dental arch being radiographed. Following this, the patient's head is moved to repeat the opposite side of the arch, the machine is swung manually about its axis to reposition the x-ray tube and film holder, the machine is again energized, and the second half arch is exposed.

Time required totals 40 seconds for the two exposures and it is anticipated that, once the technique for using the machine is perfected, an experienced operator should be able to take full mouth radiographs in three to five minutes.

Adequate density has been obtained in adult human dental radiographs using x-ray tube voltage and current of 65 kv. at 10 milliamperes. Patient radiation at various points in and about the head is reduced in this method of radiography due to the fact that a narrow beam of x-ray is used and repeated exposure of the same area does not take place as it does in conventional dental radiography.<sup>10</sup>

## RADIOGRAPHIC RESULTS

Radiograms of the entire dentition as well as the body and ramus of the mandible and the bony structure of the mandible and

Figure 3 Reproduction of 11 month survey

maxillary regions are produced (fig. 7). The presence of impacted or unerupted teeth or retained roots is shown and the general status of the alveolar bone is revealed. Fillings, bridges, etc., are shown, as in earlier roentgenographic techniques. If the canal has occurred. Information recorded in films is sufficient to establish many facts of value in many instances for specialized applications in prosthetic and surgical diagnosis. If further detailed spot films are required, these can be made as needed. The panoramic machine is not designed to supplant the conventional technique where the recording of extreme detail is necessary.

### SUMMARY

A panoramic dental x-ray machine for use in panoramic examinations has been developed and a prototype constructed. This device produces full mouth dental radiographs on a single 5 by 10 inch film using an external technique. Patient is positioned either seated or standing, beneath the moving arm of the machine, which carries an x-ray source and film holder. Rotation of this arm about its axis sweeps the x-ray source and film along the patient's head, producing a projection of the dental teeth images on the moving film. An exposure time of approximately 15 seconds is required for each side of the arch. Adequate detail is secured to obtain a diagnosis of general mouth conditions. The panoramic dental x-ray device is not designed to supplant the conventional dental x-ray machine in cases where extreme sharpness and detail must be obtained.

# TECHNIC OF CREMASTER MUSCLE DISSECTION IN INGUINAL HERNIOPLASTY

FELIX P. BALLENGER *Captain MC USA*

**T**HE PROPER method of dissecting the cremaster muscle when performing inguinal hernioplasty has been little discussed yet in many cases it presents a real problem if an adequate repair is to be accomplished. In performing inguinal hernioplasties, and also when observing other surgeons performing this operation, I have noted difficulty in accurately suturing the fascia of the transversalis muscle to the shelving border of the inguinal ligament about the spermatic cord at the internal inguinal ring when the usual methods of dissection of the cremaster fibers were used. If the cremaster fibers are split in the line of their descent or if they are allowed to continue to encircle or cover the cord structures in any manner they will invariably obstruct the proper placement of sutures about the spermatic cord at the internal inguinal ring.

## OPERATIVE TECHNIC

In order to avoid the difficulties created by the presence of the cremaster muscle in this part of the repair, I have developed a technic for dissection in this region which completely removes the obstructions caused by the cremaster fibers and also in cases of recurrent hernia and large hernia obviates excision of the cremaster in order to accomplish adequate repair. The following technic for dissection and repair of an inguinal hernia is therefore recommended as I have used it in a large number of cases with invariable ease of suture placement and excellent results.

1 The usual inguinal skin incision is made

2 The external oblique fascia is incised and opened in the line of its fibers into the apex of the external inguinal ring. This incision is carried about one and one half inches above the internal abdominal ring and well down over the pubic tubercle in the external spermatic fascia.

3 The cremaster fibers are dissected free from the inguinal ligament from the pubic tubercle to one inch above the internal

abdominal ring (fig. 1) It is important in this dissection to see that all fibers are completely detached from the inguinal ligament.

Figure 1 Beginning the dissection of the cremaster muscle. The point of the scissors is shown under the lower edge of the cremaster at this site the cremaster is detached from its origin.

This lower border of the cremaster is then elevated and the dissection continued to elevate the cremaster muscle in its entirety from the external spermatic fascia and underlying cord (fig. 2). The entire cremaster, including its origin from the internal oblique muscle, is then retracted upward. This exposes the spermatic cord covered by the internal spermatic fascia (fig. 2).

4 The spermatic cord and its internal spermatic fascia covering can then be dissected completely free from the floor of the inguinal canal from the internal abdominal ring to a point below the pubic tubercle. When this has been accomplished all areolar tissue is removed from the inguinal canal and its floor (fig. 2).

5 The internal spermatic fascia is then incised in a line with the spermatic cord and the hernia sac can easily be brought up, dissected out completely, its neck transfixed and ligated high inside the internal abdominal ring, the sac excised, and the stump

allowed to retract upward. If however, a direct hernia sac is present, it can be handled by whatever method seems appropriate, such as dissection, high ligation, and excision or by imbrication and infolding.

Figure 2 The cremaster has been elevated from the cord and the cord dissected from the floor of the inguinal canal.

8 After the sac or sacs in the case of a "Pantaloon" type have been adequately removed or imbricated, the repair can then be proceeded with. The transversalis fascia is secured in the floor of the inguinal canal with Allis forceps and the border of the transversalis fascia is sutured to the shelving border of the inguinal ligament with interrupted No 00 cotton sutures (fig 3). The sutures are placed from the medial angle lateralwards being certain to secure the first suture into the fascia overlying the pubic tubercle. As placement of the sutures upward and outward proceeds it becomes obvious that they can be placed on either side of the spermatic cord at the internal abdominal ring with ease without incorporating fibers of the cremaster muscle because the cremaster and internal oblique muscles are now being retracted upward completely out of the way (figs 3 and 4). By placing 6 to 8 sutures below and medial to the cord and 2 or 3

Figure 3 Retraction upward of cremaster muscle permits easy placement of sutures in transversalis fascia and inguinal ligament

above or internal to it, a snare repair around the spermatic cord usually can be obtained. In infants and children this layer of repair is not necessary and is omitted. I believe that many recurrences of indirect inguinal hernias occur because of inaccurate placement of sutures and failure to secure an adequate, snare repair about the spermatic cord. This defect can easily be avoided by using this technique of dissecting the cremaster and repairing the floor of the inguinal canal.

7 The spermatic cord is then replaced in the inguinal canal and the cremaster replaced over the cord and sutured to the inguinal ligament in its normal anatomic relationship (fig 5). However, if it is thought desirable the cord can be transplanted completely to the subcutaneous tissues in the Halsted repair. If the cord is replaced in the canal and the cremaster sutured over it as above described the external oblique fascia and external spermatic fascia are then closed with interrupted No

0000 cotton sutures and the subcutaneous tissue and skin closed with the same material. If the Halsted procedure is done the external oblique fascia is sutured beneath the spermatic cord.

*Figure 4. All sutures have been tied apposing the transversalis fascia to the inguinal ligament*

allowing the cord to emerge through this suture line at a point about one half to three fourths inches lateral to the internal abdominal ring. A bed of subcutaneous tissue is then sutured underneath the cord between it and the external oblique fascia and subcutaneous tissue and skin are closed over the cord, using No. 0000 cotton sutures throughout.

#### SUMMARY

A technic for dissecting the cremaster muscle from the external spermatic fascia and spermatic cord and retracting it upward along with the internal oblique muscle allows easier placement

Figure 5 The cremaster has been in tonic position and is shown here inguinal ligament

of sutures in the transversalis fascia. This technic obviates the incorporation of a suture above and lateral to the spermatic cord and makes a more accurate and stable repair of the inguinal canal floor.

This article is reprinted from the November 1955 issue of this Journal. Because of a printing error had robbed the illustrations of some of their effectiveness in giving the reader a clear understanding of the important new technic described.—Editor

# THE PASSIVE-AGGRESSIVE PERSONALITY

RICHARD G SINGER *Lieutenant Commander MC USNR*  
CHRISTOPHER C SHAW *Captain MC USN*

**A**LTHOUGH the passive-aggressive individual is not well described in the psychiatric literature he is encountered with considerable frequency at military sick call. This chronic complainer presents knotty problems in medical administration and his treatment and disposition provoke considerable tension. Before enlarging on the nature of these difficulties and presenting suggestions for the management of the recalcitrant patient, a brief review of the features of this character disorder is in order.

According to Hodge: "The passive aggressive character is the man you don't like." This is the ideal summation. The unpleasantness of this type of personality prompted H. G. Wells to refer to such people as "common humanity unmitigated." They are chronic complainers who imply that their medical problems are largely unappreciated and that the physicians have acted in a thoroughly incompetent and poorly intentioned manner. Beneath a thin veil of reluctant courteousness their attitude of surliness puts other people on the defensive.

The actions of the passive aggressive individual are characterized by an angry reluctance and a calculated inefficiency. He grumbles and protests, he procrastinates, but he does not openly accuse or rebel. He appears pained by his work, his position, his general circumstances, and his ailments. He will never admit to enjoying himself despite the fact that someone might actually catch him in the act. His whole life is one of dedicated suffering for which he feels other people are wholly responsible. The passive aggressive personality makes innumerable demands which when gratified result not in pleasure but only in more demands and new conditions. He resents everything (even himself) and verbalizes the conviction that life holds nothing for him and that he might as well be dead. But because he disguises his expressions of hostility, he cannot be openly accused of disobedience.

From the military point of view, this cantankerous attitude often takes the form of a marked reluctance to work, which the offender

frequently bases on a deep and sincere conviction that he is incapacitated by some illness such as excessive and intractable headaches, extreme anxiety, "bad feet," or varicose veins which prevent walking, marching, or working. The tendency of such individuals to "black out" is probably an exaggeration of a mild spell of vertigo. Passive aggressive personalities are very quick to use such a symptom as "blacking out" in an effort to convince their superiors that it is unsafe to use them in a job where such a spell might endanger their lives or those of their shipmates.

Usually the passive aggressive personality is regarded as a rather unwelcome member of any military group, and his superiors are prompt in transferring him to some other unit to rid themselves of an "unwilling dragon." His friends tend to react in a similar manner, since his social relations can be described by the phrase, "Whom he loveth, he chasteneth." In summary, the passive aggressive character is surly, complaining, tends to procrastinate, and implies that other people are treating him badly. This man is not a malingerer but rather a person who has minimal complaints which he over exaggerates and to which he is helplessly compliant. Despite his undeniable unhappiness he is basically as competent as most other men, yet his production is far below average. He suffers from poor motivation rather than from physical or emotional incapacitation.

Generally there are a succession of events which occur in the military career of a passive aggressive individual and finally bring him to the psychiatrist's office. The first step in this direction frequently is taken aboard ship where it is noted that the man seems to be excessively nervous and ill. With all good intentions, his corpsman frequently refers him to sick call, either at sea or at a nearby shore based dispensary, for an evaluation of his excessive headaches or anxiety. The man is seen by the medical officer, who makes an honest attempt to treat him by means of accepted recommendations and medications. The patient will not accept this advice and generally returns to sick call on several subsequent days complaining that whatever has been recommended has been to no avail and that his condition is largely intractable. Accordingly, the medical officer feels that this intractable patient should perhaps be seen by a specialist and refers him to a nearby hospital for consultation. In the hospital the same pattern of events is repeated, the man is given specific treatment and equally specifically fails to react. At this point he is referred for neuropsychiatric consultation because of his excessive concern for symptoms that cannot be clinically substantiated. Medical recommendations result in a long series of impasses because the passive aggressive patient expects and then demands some type of magical cure. If this is not forthcoming

ing in the hospital he frequently seeks advice on the outside from an osteopath, a chiropractor or "faith healer." Finally, the specialist in the hospital reaches the point where he feels that nothing can be done for this patient and the man is discharged to duty "under duress." He then may write to his mother for redress or to his Congressman demanding an "investigation" of alleged flagrant professional incompetency.

### HOSTILITY

In order to clarify why this particular individual demands such minute medical attention it is necessary to return to his basic personality structure and consider what effect it has on other people. Beneath his veneer of courteousness the passive aggressive character is deeply hostile. If the physician is not aware of this, resentment or tension may develop within the doctor who is dealing with such a character disorder. The first person to fall into this particular trap is the corpsman who is attached to the man's unit. Due to the anxiety that is provoked by the man's repressed hostility the corpsman's first impulse is to try to rid himself of the passive-aggressive patient. Although he may be convinced that this patient is not excessively ill and does not require further medical attention the patient usually demands further treatment. To avoid further useless discussion, the corpsman's tendency is to relieve himself of his tension by passing the patient on to the medical officer whose immediate inclination is to please the patient's demands as much as possible. If the doctor attempts to explain to the patient the nature of his symptoms suddenly the situation becomes more complicated and the medical officer finds himself involved in a highly personalized situation to the delight of the passive aggressor. Perhaps without his being aware of it the physician's own hostility is activated by the basically hostile attitude of the patient. This frequently produces a "guilt complex" in the medical officer when he finds himself actively disliking a patient. To remove the cause of his "guilt" his tendency is to pass the patient on to some other physician preferably by the technique of a "consultation." And so the medical merry-go-round gets underway affording the patient an ideal opportunity to play both ends against the middle and vice versa, much to the delight of his ego!

Passive aggressive personalities are very difficult to stand up to because they are basically unreasonable and because their hostility tends to activate anxiety in others. The man's behavior is such that he appears to most lay people as definitely being a sick man. The physician naturally feels that to be firm with such an individual and force him to return to duty might in some way appear to observers as being hardhearted. Because of his own fear of arousing hostility in the patient his inclination is to refer

him to someone else. Thus we see that both the corpsman and the medical officer tend to follow the path of least resistance in ridding themselves of the passive aggressive patient by complying with his demands and usually passing him on for further medical considerations.

Passive aggressive personalities frequently exhibit very strong urges toward earning attention and demanding retirement from military service on the basis of their so called disabilities. They are able to persist and will go to elaborate lengths in attempting to gain these ends. Occasionally they are successful, but their success is both a burden on the taxpayer and a travesty of justice. Hospitalization of these individuals is a needless and inexcusable expense. To the cost of his hospitalization is added the fact that the man is not producing anything while he is on the sick list, so that in the last analysis the cost of caring for such an individual far outweighs any monetary value of his wholly unsatisfactory military service.

It is of interest to note some of the implications of this pattern of events that takes a man from his work, puts him on the sick call, and finally refers him to a nearby medical center for examination by specialists. The first consideration is the fact that this man tends to lose a great deal of time from his work and that facilities, such as transportation, are required to move him around to the various points of medical examination. This "special attention" is a form of notoriety which the passive aggressor soaks up like a dry sponge. Such domenor in the long run has a bad effect on the morale of his shipmates because it puts the medical department in a bad light and lends his shipmates to believe that they, too, can "get away with it."

#### EFFECT ON GROUP MORALE

The greatest difficulty in dealing with such a man is the fact that he can influence morale in his unit by impugning the motives of other people. He can very cleverly inject a quality of caustic wit into his remarks that makes his shipmates feel guilty for their enthusiasm for their work. The man tends to make all duty aboard ship seem rather ridiculous and implies that anybody who is willing to do it is a fool. Such an individual has a diabolical ability to kill or to cripple group morale. He then gloats over his destructive prowess and looks about for new fields to confuse and conquer.

Generally, the passive aggressive personality is quite clever in using his complaints to create friction between the medical department and the people who command the various units. This friction frequently comes about because the office, ship, barracks, or battalion would like to be rid of this reluctant worker and chronic

complainer Yet the medical department insists that the man is well enough to work and sends him back to duty This also creates rather bad personal and public relations among the men since the passive aggressive character takes the attitude that he is being forced back to duty despite the fact that he is obviously a sick man Because of the persistence of such an individual's complaints, frequently considerable sums of money are expended in assuring him that he is getting a really fair examination before being forced back to duty Unfortunately, as these antics continue, the man becomes increasingly aware of the advantage he holds He constantly leans toward being ill and shows when ever possible that he is basically unable to work The man is aware that the weight of opinion among the crew is on his side and to a certain extent this makes it more difficult for the officers aboard the ship to enforce discipline His all too obvious suffering implies that the officers are callous and unappreciative of the fact that he is ill The man therefore becomes a morale breaker by assuming an attitude of righteous indignation and hostility toward the military service in general and against the military medical department in particular Finally this may result in expensive litigation and demands for a pension even after he has been discharged from active duty

### PSYCHODYNAMICS

Dynamically most of the character traits in this disorder seem to stem from only a few sources One is a deep disappointment in love which the individual suffered at a very early age His provocative behavior probably was originally directed toward that parent to whom he was most attached but who failed to reciprocate his feelings These provocations in some dim animal way were intended to elicit an affectionate response from the love object and at the same time to express strong hostility associated with the frustrating situation Such a child also feels (without the capacity to intellectualize it) that the overt expression of love from the parent considerably reduces the state of tension and anxiety which the individual is chronically burdened with Unfortunately with the passage of time the individual's demands for affection become so exaggerated that there can be no appeasement which naturally leads to further tension frustration, and provocative behavior in that order Thus, the man's adolescent behavior becomes deeply consolidated in his character structure and serves the dual functions of defense and gratification The defense function would be the petulant conviction that he is abused thus warding off the feeling of his deep need to be loved and the gratification is the chronic disguised expression of hostility that arises because of his frustrations

## TREATMENT AND DISPOSITION

Every patient who comes to the dispensary or sick call is certainly entitled to a medical examination regardless of his character structure or defects previously entered in his health record. It is always important to bear in mind in these cases that men with psychologic problems can also have a definite organic illness. Thus, the passive aggressive's backache may occasionally turn out to be caused by a kidney stone or some related pathologic process. Therefore it is important to record as clearly as possible the results of the physical examination. Once a passive aggressive personality has had his physical complaints evaluated, he should not be referred for further examinations by specialists or hospitals unless such examinations are definitely needed. At this point it is of vital importance for the medical officer to have the courage of his clinical convictions and not refer the man for further examinations just to be rid of him. An unwarranted consultation may consolidate the man's complaints and convince him irrevocably that he really is ill and that he has received inadequate or shabby treatment. Sooner or later he must be told quite firmly that he is fit for full duty and returned to it immediately. At times, this is very difficult to do in the presence of his manifest suffering, even though it be more apparent than real.

Because of the tendency of the passive aggressive personality to seek litigation and to complain to people in high political positions, the medical officer's record of clinical findings and therapy should include an opinion as to whether or not the man is fit to return to duty. Generally, passive aggressive personalities are very quick to use their medical records in the further elaboration of their complaints. They have a morbid interest in their health records as a springboard from which to launch their attacks on the integrity of the Medical Corps or even on the efficiency of the Navy as an organization vital to the defense of democracy. One cannot necessarily regard their attitudes as those of malingering because these men have convinced themselves that they are ill and that they are not being adequately treated.

Once the medical officer has firmly insisted that the man return to his duty, very often the patient will be openly hostile to the physician. Occasionally, such a passive aggressive personality will react with apparent pleasure to the fact that he is being forced back to work. Dynamically, this pleasure is the result of a reduction in overall tension as a consequence of his hostility now being concentrated on the physician, who by his firmness has become the target for the patient's vituperation. This reaction represents a somewhat masochistic component of this defect in character structure. Generally, when a man is forced to return to

full and active duty it is necessary to notify his commanding officer of the circumstances and assure him that the man is fit. Returning a man to duty under these circumstances puts him in a position of facing disciplinary action for his continuing failure to work. Because passive aggressive personalities realize the imminency of punishment and seek to avoid overt conflict they respond quite favorably to this type of situation. Provided one discounts their grumbling they seldom get into trouble once they are made to realize that the "chips are down." Although ordering him back to duty may appear to be a rather hardhearted solution of his medical problems it is the only salutary action. Whenever possible it is a good idea to see these men for a few follow up sessions in psychotherapy.

All that one can hope to accomplish in a short term psychotherapy is to transfer the petulance and provocation (which are sadistic aggressions turned inward) into overt outwardly directed hostility. This disturbs the economy of the symptom (or system) in terms of ego-function by disrupting its equilibrium. The patient dissipates tension by being outwardly angry with the physician and begins to feel the difference between this and his usual petulant and procrastinative behavior. This is probably the reason why some of these passive-aggressives react favorably to the physician's firmness on sick call—they overtly become angry with him and this relieves tension to some degree. Thus pleasure and pain become juxtaposed in their functioning. The passive aggressive reacts to other people's anger and irritation as if it were an expression of affection. This is probably related to childhood experiences in which the two were closely associated for example a hearty spanking being followed by expressions of affection.

During these psychotherapeutic interviews the passive aggressive continues to be extremely complaining. Whatever suggestions are made are met with a series of impasses constructed by the patient as defense or escape mechanisms. Generally there is no apparent progress during psychotherapy but the clinically oriented psychiatrist notices that the patient seems gratified by the attention he is receiving from the physician. Once dealt with firmly the patient becomes more tractable about returning to work. One finds by calling his ship that he is relatively happy and productive although he will never admit that he is feeling better. Always with this type of personality bluntness is the best mode of approach or attack. Once a concession is made the floodgates are opened to a veritable deluge of demands for additional concessions. It is dangerous to spar with a passive aggressive patient. The only hope of success is to be completely candid and almost brutally frank.

Hospitalization of such individuals defeats its own purpose because it affords them a golden opportunity to consolidate their

complaints and provocative behavior. These patients are chronic "sufferers," and they rarely feel that there is anything bright in their future. Because of these attitudes these men make relatively little progress when assigned to a psychiatric ward, and almost invariably they collapse as soon as they have been discharged from the security of the hospital. They cannot make a satisfactory adjustment to the facts of life nor adequately cope with the stresses and strains of the social structure because they are their own worst enemies.

If the individual with a fixed passive aggressive personality is basically intractable and cannot be returned to duty despite all his numerous complaints, it may be necessary to separate the man from military service for the "convenience of the Government." Even the threat of disciplinary action may fall on deaf ears, in which case the man remains a very reluctant worker and is a chronic thorn in the side of the people who are trying to run the organization. Because of his low morale, he remains an unproductive worker, which of itself is evidence that he is psychologically unfit for military duty.

### CONCLUSIONS

In the last analysis the basic trouble with such a passive aggressive personality is that the man has extremely poor motivation. He uses elaborate symptoms as an excuse for his failure to adjust to military service, and he places the blame on "the brass" in general and the medical officer specifically. People who are unenthusiastic and recalcitrant simply do not belong on the varsity squad. Ideally, they should be kept out of the service whenever possible. However, such a person, when appearing for his premilitary screening, very often seems enthusiastic about military training. Such enthusiasm, however, is short-lived, once the initial glamor has faded and the "heat is on." Since the recruit tends to keep his character traits in abeyance during his initial interview, the first examiner has no way of really demonstrating the underlying character defect. Once on active duty, however, the passive aggressive soon reveals his surly behavior, his pro-posterous complaints, his irascible, cantankerous attitude, and his reverse negative motivation.

The only way to deal with passive aggressive personalities is first to rule out the possibility of any definite organic lesion as a basis for their "symptoms." Then they must be firmly returned to duty rather than referred for further examinations and hospitalization, which are and would continue to be entirely unwarranted. If the individual persists in his recalcitrancy, he should be separated from the military service without benefit of retirement for physical or mental illness.

## Clinicopathologic Conference

Brooke Army Hospital Fort Sam Houston Tex.\*

### ADRENAL INSUFFICIENCY QUADRIPLÉGIA AND COMA

**Summary of Clinical History** A 64 year old white male retired Army officer had been in apparent good health until September 1949 at which time he developed bloody diarrhea and fever while traveling in Mexico. Following recovery from this illness he began to have weakness, easy fatigability, nervousness and difficulty with coordination. In July 1950 he was admitted to an Army hospital and diagnoses of toxic hyperthyroidism hook worm disease, and chronic larvngitis were made. Each of these entities responded well to treatment, and the patient was discharged on maintenance propylthiouracil therapy. Outpatient urologic evaluation because of urinary frequency resulted in the diagnosis of benign prostatic hypertrophy and a recommendation for transurethral prostatic resection. The patient declined an operation and was followed in a civilian clinic during the latter months of 1950. There it was felt that many of the patient's complaints were on a functional basis. Benign rectal polyps were discovered however, and these were fulgurated. He was admitted to a civilian hospital in December 1950 with the chief complaints of weakness and nervousness. Because of additional complaints of tibial pains and the discovery of consistently elevated acid phosphatase determinations (10.5 to 12.5 Bodansky units) he was transferred to an Army installation for further evaluation on 3 January 1951. Within nine days after admission to the Army hospital progressive nausea vomiting, and hypotension developed and

Brig Gen Stuart G Smith MC USA Commanding General From the Laboratory Service Col George J Miller MC USA Chief

for the ensuing month the patient received supportive therapy, penicillin, and Doxa Acetate (brand of desoxycorticosterone acetate). On 16 February the patient began to have daily febrile episodes, to 100° or 101°F. Blood pressure remained at about 66/30 mm Hg. Adrenal cortex extract and cortisone were then administered daily as well as maintenance doses of Doxa Acetate, and marked clinical improvement occurred within the next six days. Thereafter the patient was maintained on daily Doxa Acetate and cortisone, he was discharged from the hospital on 3 July on these drugs, along with supplemental salt and testosterone. Pertinent laboratory studies during this period of hospitalization indicated persistently depressed serum sodium determinations (125 to 140 meq/l), an average daily urinary 17-ketosteroid level of 3 mg per cent, an abnormal eosinophil response to corticotropin (ACTH) and epinephrine, positive Robinsohn-Power kepler tests, and a distinctly flattened glucose tolerance curve.

The patient was rehospitalized briefly in November because of frequent bouts of vertigo, tinnitus, and staggering gait. Discharge diagnosis was "otitis media, acute, improved." In May 1952 he began having generalized convulsive seizures which characteristically lasted for 10 to 15 minutes, were not associated with unconsciousness, disappeared spontaneously, and resulted in brief, postseizure dizziness. His final admission, to this hospital, was on 16 May 1952.

The patient's past, social, and family histories were essentially noncontributory.

**Physical Examination.** Physical examination upon admission disclosed a temperature of 101.2°F, a pulse rate of 126 per minute, and a blood pressure of 160/90 mm Hg. Significant abnormal physical findings included a barely palpable, nontender liver, a small, firm nodule of the left epididymis, absence of abdominal reflexes, slight motor weakness of the left extremities, and generalized tan hyperpigmentation of the skin and mucous membranes. Save for a mild normochromic, normocytic anemia and a corrected sedimentation rate of 31 mm per hour, admission hemogram was essentially within normal limits. Urinalyses were not remarkable. Electrolyte studies and fasting blood sugar levels were within limits of normal.

**Course in Hospital.** The clinical impression upon admission was that the patient had sustained a cerebrovascular accident. Because of primary complaints of weakness, daily dosages of cortisone and Doxa Acetate were increased. On 25 June the patient complained of hoarseness, difficulty in walking, and unsteadiness while standing. On 6 July bilateral Babinski signs were elicited, and spinal fluid protein level was 111 mg per cent. Shortly thereafter urinalyses repeatedly demonstrated albumi-

nuria, hyaline casts and microscopic hematuria. Electrolyte studies and leukocyte counts remained within normal limits. On 8 July the patient had a typical left sided Jacksonian seizure, and spinal fluid studies including manometric recordings, were normal save for total protein concentration of 110 mg per 100 ml. No organisms could be cultured from the spinal fluid.

Marked weakness of the left extremities, marked apathy, and slurred speech ensued, followed by semistupor on 14 July. Beginning on about 10 July the patient's blood pressure gradually decreased, pulse rate increased, and low grade fever recurred. Slight nuchal rigidity and flaccid paralysis of the left upper extremity developed. The neurology consultant additionally noted bilateral Babinski signs, right upper extremity spasticity, right-sided hyperreflexia and slight right facial weakness. Dyspnea and cyanosis appeared on 14 July. For the following two days neurologic findings were exceedingly variable. The patient died in coma on 16 July 1952, almost three years after the initial onset of symptoms.

#### CLINICAL DISCUSSION

Doctor Hollander.\* This patient's difficulties began with diarrhea. If, as we believe, the patient had adrenal insufficiency of prolonged duration, it is possible that this diarrhea constituted the initial symptom. Gastrointestinal symptoms are often the initial event in the relentlessly downhill course of Addison's disease. It is possible that the bloody character of the diarrhea could be ascribed to the rectal polypa. It is further conceivable that the symptom triad of diarrhea, weakness, and nervousness encountered early in this patient's medical history could be ascribed to hyperthyroidism. Hyperthyroidism is about 10 times more frequent in people with Addison's disease than in people with intact adrenal function.

Two possible explanations for this relationship have been advanced. One can experimentally demonstrate the reciprocal relationship between the adrenals and thyroid by the depression of radioactive iodine uptake by the thyroid following the administration of large quantities of cortisone. Secondly, hyperthyroidism *per se* acts as a stressful systemic phenomenon and forces increased adrenal activity. Clinical evidence of hyperthyroidism abated in this patient. This fact would be of clinical importance in a patient with Addison's disease since he could not be expected to tolerate well the added stress of thyroid hyperfunction.

I assume acid phosphatase determinations were done because of ribial pains. Since I feel that insufficient practical evidence is present to seriously suspect primary prostatic malignancy, the elevated acid phosphatase levels might occur by either of two mechanisms. First

\*Capt. Vincent P. Hollander, USAF (MC) (b). Chief, Biomedical Section, School of Aviation Medicine, Randolph Air Force Base, Texas.

temporarily elevated levels may be obtained if determinations are performed shortly after rectal examination and prostatic palpation or massage. Second, similarly elevated phosphatase levels may be produced by a poorly understood mechanism whereby the blood sample is allowed to stand at room temperature, perhaps for 24 hours or so before the chemical procedure is started. In a patient with Addison's disease, tibial pains might actually be on the basis of muscle cramps secondary to excessive salt loss associated with increased water ingestion. Co-existing rheumatoid disease might possibly account for these pains. There is a statistically significant co-existence of Addison's disease and rheumatoid arthritis. Rheumatoid disease, however, appears unlikely in the patient under discussion.

The patient's hoarseness merits some comment. Laryngeal muscular weakness commonly is found in patients with Addison's disease. The diffuse hyperpigmentation described in the protocol also appears characteristic of Addison's disease, and we need not seriously consider other differential causes of pigmentation such as hemochromatosis, argyria, acanthosis nigricans, and the like.

Let us review the salient signs and symptoms indicative of Addison's disease. A majority of these indications were manifest in the case under discussion. We may tabulate weakness, easy fatigability, hoarseness, weight loss, dehydration, gastro-intestinal disturbances such as anorexia, nausea, vomiting, and diarrhea, hypogonadism, hyperpigmentation, hypotension, and nervous and mental disturbances. The latter findings are often difficult to evaluate in patients with Addison's disease. The occurrence of psychiatric aberrations is known to most of us, but less widely appreciated are the neurologic findings, including electroencephalographic changes, which occur so frequently and which may simulate localized cerebral or spinal cord disease.

We may postulate that some of the neurologic abnormalities can be attributed to hypoglycemia. Hypoglycemia in degrees ordinarily well tolerated by normal individuals may produce marked neurologic difficulties in patients with Addison's disease. In other words we may say that these people are "hypoglycemia sensitive." Neurologic difficulties may also be ascribed to "wet brain" resulting from adrenal steroid therapy, particularly to Doca Acetate therapy. Lastly, many diseases not uncommonly affecting the central nervous system such as tuberculosis, tumors, cryptococcosis, and histoplasmosis may have anatomically demonstrable adrenal involvement and thus produce the picture of localized central nervous system disease combined with Addison's disease.

The laboratory diagnosis of Addison's disease warrants some discussion. We are all aware of the commonly employed laboratory evidences such as hyponatremia, hypochloremia, hyperkalemia, hypoglycemia, flat glucose tolerance curve, decreased urinary 17 ketosteroids and 11 oxycorticosteroids, positive Thorn eosinophil test, and positive Robinson-Kepler-Power water loading test. To this list

may be added decreased plasma corticoids positive salt deprivation test and increased insulin sensitivity. Other clinically useful diagnostic modalities include decreased cardiac size abnormal electroencephalographic and electrocardiographic tracings and evidences of impaired renal function such as decreased renal blood flow decreased glomerular filtration and abnormal uric acid excretion. I would like to comment briefly on some of these laboratory procedures in adrenal insufficiency suspects.

Hyponatremia may not be present in patients with Addison's disease particularly with Doca Acetate therapy. Interpretation of serum sodium levels necessitates correlation with chloride and bicarbonate levels as well as the clinical status of the patient.

Serum potassium determinations in uncomplicated Addison's disease are out of particular diagnostic aid and levels may be low rather than high in patients receiving Doca Acetate.

Low urinary excretion levels of 17-ketosteroids and 11-oxy corticosteroids are characteristically obtained in Addison's disease. Decreased excretion of 17 ketosteroids however may be seen in other debilitating diseases. Low urinary excretion of 11-oxy corticosteroids is not pathognomonic of Addison's disease since the test widely employed is not entirely specific for these substances.

In the Thorn eosinophil test the use of ACTH yields less consistent results than the use of epinephrine. With ACTH of course in the presence of normally responsive adrenal glands a 60 to 70 per cent fall in circulating numbers of eosinophils can be expected. In Addison's disease a significantly diminished eosinophil response is obtained. One word of caution. Commercially available ACTH preparations commonly have significant antidiuretic properties and in judicious usage may lead to adrenal crisis in Addisonian patients by virtue of prompt water retention and sodium dilution.

Methods for measuring plasma corticoids are now available and the method of Nelson and Samuels<sup>1</sup> is quite useful. Normal blood values of 4 to 10  $\mu\text{g}/100\text{ ml}$  are reported with significantly reduced levels in patients with Addison's disease. In clinically questionable cases of Addison's disease however this determination has limited diagnostic value.

Increased insulin sensitivity has been described in patients with Addison's disease. The test is not without hazard however since these patients are inordinately sensitive to insulin and may go into irreversible adrenal crisis from the insulin test doses usually employed. An insulin glucose tolerance test devised by Scott and Engel is a safer diagnostic procedure.

The water loading and salt deprivation tests may induce acute adrenal insufficiency states for diagnostic purposes. These procedures are out of the question in this day when other applicable laboratory tests are available.

In summation, I feel that the patient definitely had adrenal insufficiency or Addison's disease. In view of the neurologic symptomatology and elevated spinal fluid protein it is my guess that rather diffuse central nervous system disease existed as well. To equate the two major pathologic processes in this patient, namely adrenal and cerebral disease we may postulate the presence of a disease process capable of producing these changes such as tuberculosis, histoplasmosis, or cryptococcosis. I tend to discount the possibility of neoplastic disease with widespread metastases since I have no good indications of a possible primary anatomic site.

Doctor Lind: Doctor Hollander, you mentioned neurologic findings encountered with Doca Acetate therapy. Did you mean hypertension? To what may cerebral edema be attributed?

Doctor Hollander: I meant severe hypertension, sodium retention, diffuse edema, and cerebral edema. Much of the neurologic picture seen in patients with Addison's disease may well be attributed to Doca Acetate therapy. In a group of 30 patients on whom bilateral adrenalectomy had been performed we have found it necessary to use Doca Acetate only once. Although we appreciate the fact that an occasional patient will require Doca Acetate because of hypotension which can not be corrected by cortisone we feel that cortisone therapy alone is the treatment of choice.

Dr. Hollander's diagnosis:

Addison's disease, possibly secondary to disseminated cerebral tuberculosis, histoplasmosis, or cryptococcosis.

#### PATHOLOGIC FINDINGS

Doctor Sulak: Following correlation of clinical and necropsy data, death was attributed to adrenal cortical insufficiency, terminal pulmonary edema and congestion, and acute bronchopneumonia of the lower lobes bilaterally. Approximately three weeks before the patient died, a small, ulcerative lesion of his upper gum was biopsied and the basic disease responsible for the protean symptomatology was identified.

At necropsy the significant findings on external examination were those of emaciation, diffuse brownish hyperpigmentation of skin and mucous membranes, the healing gum lesion, and a firm 2 cm nodule within the upper pole of the left epididymis.

The most significant gross pathologic changes affecting internal viscera in approximate order of decreasing severity, were found within the adrenal glands, brain, kidneys, left epididymis, tricuspid cardiac valve, upper gum, liver, spleen, and random abdominal lymph nodes. These changes may be described briefly as solitary and multifocal, occasionally confluent granulomatous nodules with varying degrees

\*Col. Carl J. Lind, Jr., MC, USA, then Chief of Laboratory Service.

\*Maj. Michael H. Sulak, MC, USA, Laboratory Service.

of caseous necrosis. The adrenals were almost totally destroyed and at the opposite end of the spectrum the hepatic splenic and nodal lesions were barely discernible by the naked eye. Microscopically these lesions were productive and exudative granulomatous processes produced by minute ovoid intracellular organisms morphologically characteristic of *Histoplasma capsulatum*. Post mortem cultures of heart blood and adrenal and cerebral tissues yielded characteristic colonies of *H. capsulatum* and microscopic morphologic features of the cultivated organisms confirmed these observations.

Multiple lesions were scattered throughout the cerebral medullary substance. The largest single lesion measured approximately 2 cm in diameter and occupied the right optic thalamus (fig 1).

Figure 1 Coronal section of fresh brain at the level of the mamillary bodies showing granuloma occupying the right optic thalamus

Oil immersion photomicrographs of tissues stained by the periodic acid Schiff technic disclosed myriads of the ovoid encapsulated organisms measuring 2 to 4 microns in diameter clustered within macrophages and parasitized parenchymal cells and lying freely in tissues. Figures 2 and 3 show typical fields with adrenal and kidney lesions respectively. It will be noted that in figure 2 empty ring forms predominate.

Figure 4 shows the microscopic characteristics of the mycelial growth phase of the organism with a feltwork of thin septate hyphae and the pathognomonic tuberculate chlamydospores the spore-bearing bodies resembling a medieval mace

Figure 4. Photomicrograph of culture mount showing characteristic tuberculate chlamydospore of *H. capsulatum*. (Lactophenol cotton blue stain,  $\times 2900$ )

If given some degree of scientific latitude we may say that the diseases histoplasmosis and tuberculosis manifest many strikingly similar clinical and pathologic characteristics. These similarities will become more apparent in a brief discussion of histoplasmosis as an entity of increasing clinical importance particularly within the United States.

Darling<sup>2, 3</sup> in Panama described the first three clinical cases of histoplasmosis in 1905-1907. He felt that the etiologic organism was a protozoan. It wasn't until 1934 that the causative agent was conclusively demonstrated to belong to the *Fungi imperfecti* by De Nonbreun<sup>4</sup> and by Hansmann and Schenken.<sup>5</sup> Until the decade 1940-1950 the disease was considered an invariably fatal systemic process characterized by reticulo-endothelial granulomatosis. During this period however an increasing body of critical evidence made it clear that histoplasmosis was much more widespread than had been previously supposed and that a large endemic area existed in the United States in the area comprising the Mississippi-Ohio valley. Largely through the studies of Nelson,<sup>6</sup> Furcolow,<sup>7</sup> Smith,<sup>8</sup> Christie,<sup>9</sup> and others it was made increasingly apparent moreover that a benign form of the disease was of much greater statistical incidence than the disseminated fatal variety. Repeated demonstrations of non-tuberculous pulmonary calcific

lesions with negative tuberculin and positive histoplasmin skin tests in asymptomatic patients living in the east central United States fostered and fortified this concept of the common benignity of histoplasmosis.

Studies on the epidemiologic aspects of histoplasmosis have yet to demonstrate human-to-human or animal-to-human modes of transmission. Emmons<sup>10</sup> demonstrated the saprophytic existence of the organism in soil in endemic areas, and many different animal species in these areas have been found with the natural infection. The inhalation of air-borne spores is considered to be the means by which humans most commonly come into contact with the infective organism, largely because of the frequency of inactive and healed pulmonary lesions. Much as in pulmonary tuberculosis reinfection or progressive dissemination may occur with serious, often fatal consequences.

The reticulo endothelial system is always affected in the disseminated processes. A granulomatous response is elicited within host tissues with formation of characteristic productive and exudative lesions containing varying numbers of the yeastlike organisms. These changes in tissues represent the yeast or parasite phase of growth of *H. capsulatum* in contradistinction to the mold or mycelial phase obtained on artificial media at room temperature.

Within recent years the use of the periodic acid Schiff staining technique with its several modifications and the use of the Girdley stain has greatly facilitated the histopathologic diagnosis of histoplasmosis as well as other mycotic diseases.

With dissemination of the disease any and all viscera may become involved. The adrenals, however, almost as commonly as the lungs and reticulo endothelial structures, are sites of involvement in disseminated histoplasmosis. Accordingly, the syndrome of Addison's disease may often dominate the clinical picture, as was true in the case under discussion today.

Despite the increasing facility of tissue diagnosis by the newer staining techniques previously mentioned, I believe that the use of tissue diagnosis to the exclusion of culture studies is undesirable. Inherent in the histologic diagnostic method are several pitfalls. There is the possibility of overlooking the organisms when they are present in small numbers. The very diminutiveness of the organisms leads to confusion with Leishmania bodies and with cellular debris and other artifacts, particularly calcified particles.

Within the past decade serologic tests for diagnostic purposes have come into existence and are enjoying increasing use. These include complement fixation tests using antigens prepared by various methods, colloidal agglutination, precipitin and sheep hemagglutination procedures. These tests at the present time appear to have some serious limitations. One of these limitations is the frequent occurrence of cross reactions with blastomycosis and coccidioidomycosis. Never-

theless positive serologic reactions with progressively rising titers in active forms of histoplasmosis are held to be of diagnostic significance by most investigators

The widely employed histoplasmin skin test is usually interpreted in much the same fashion as the tuberculin test namely that a positive reaction indicates past or present contact with the organism and that a negative result is obtainable in advanced cases of histoplasmosis

Culture of blood bone marrow and pertinent body fluids remains our diagnostic procedure of choice Adequate mycologic diagnosis necessitates growth at 37 C as well as at room temperature with production of both the yeast and mycelial growth phases respectively Conversion of one phase of growth to the other is certainly a valuable adjunct to laboratory diagnosis Blood agar Sabouraud's dextrose agar cornmeal agar and broth are the media most widely employed Microscopic examination of lactophenol cotton blue culture mounts for morphologic identification is a further necessary step in laboratory diagnosis Identification of the pathognomonic tuberculate chlamydospores (fig 4) firmly establishes the diagnosis

In summation the major laboratory adjuncts to clinical diagnosis of histoplasmosis are those of blood and bone marrow cultures tissue examinations serologic tests and skin tests

Finally with apology to Doctor Hollander since no clues were given in the protocol as to the nature of the disease producing the syndrome of Addison's disease we may conclude that the patient's major difficulties were produced by widely disseminated histoplasmosis manifested notably by adrenal and cerebral involvement

#### Pathologic diagnosis

Widely disseminated histoplasmosis with bilateral adrenal destruction and multifocal cerebral lesions

Doctor Lind Would you say a few words about the status of therapy in histoplasmosis?

Doctor Fox: Surgical intervention of course could be beneficial or curative in anatomically localized lesions In the three cases of disseminated histoplasmosis at this hospital the vanillate compounds were tried as described in the pediatric literature These compounds have fungicidal properties and are used in some industries as food preservatives We had no appreciable success with these agents in these cases Promin (brand of glucosulfone sodium) stilbamidine isethionate Atrabrine (brand of quinacrine hydrochloride) and most of the antibiotics available to us to the present time have also proved ineffectual Several reports demonstrating clinical improvement by splenectomy in those patients having hypersplenism have dotted the literature here and there Immunization procedures have not proved fruitful In short no really effective and certainly no definitive therapeutic agents are available to us at the present time

## GOOD BUT NOT HELPFUL ADVICE

The value of the good advice of the physician can be judged by considering the nature of that advice. And it should be observed that in regard to the prevention of heart disease the advice of the personal physician corresponds to the precepts available for other methods of education and propaganda which might be used in preventive programs. By and large these precepts are common sense generalities—"don't overdo things" "practice moderation in all things" "avoid violent emotions" "stop smoking" (maybe) "get a good vacation every year" and so on. These platitudes are harmless and even admirable, but there is not the slightest guarantee of their virtue for the prevention of heart disease.

## DEPENDENTS' MEDICAL CARE ACT

PAUL I. ROBINSON *Major General MC USA*

**F**OR YEARS it has been known that dependents of many active members of the uniformed services were not able to avail themselves of the medical care which was provided in hospitals of the military services. Recently, it was estimated that some 800,000 dependents (40 per cent) were so affected. Care in military and Public Health Service hospitals was rendered on an availability basis and such care was a privilege and not a right.

In many fields of labor and industry, health plans have grown up during the past several years. A goodly proportion of our citizens provide for their hospital and physicians care by prepaid insurance and health plans. One third of all members of the armed services were returning to civilian life each year and incentives were needed to stabilize careers.

These facts were taken into consideration in the formulation of a bill concerning which when he signed it into law, the President of the United States said: "I have today approved with great satisfaction the directive under which the military dependents' medical care program will operate beginning December 7, 1956. Prior to this time, at least 40 per cent of our service families were unable to receive adequate medical care from the Government. This important improvement assures hospital care at all times to the wives and children of active duty personnel. It removes one of the greatest sources of worry to our servicemen and servicewomen around the world."

"A significant new feature of this law authorizes the use of civilian hospitals and facilities for the immediate families of active duty servicemen. The cost to a service family for hospitalization in any facility, civilian or military, will be limited to a payment of either \$25 or an amount equivalent to the subsistence charge of \$1.75 per day, whichever is the greater. For this charge, all hospital services and doctors' fees for the period of hospitalization are covered. This program also continues the provision for medical care for the dependents of both active and retired personnel in military facilities on a space available basis."

Presented to the Society of Medical Consultants to the Armed Forces at Washington, D. C. on 26 November 1956.

From the Office of The Surgeon General, Department of the Army, Washington 25, D. C.

"I have been personally interested in this important program since its inception. I feel strongly that this important measure will have a far reaching effect on service morale at home or on our widely flung posts, ships, and bases around the world, and thus effectively strengthens the defense of our country."

The Dependents' Medical Care Act became law on 7 June 1956, to be made effective on 7 December 1956. It provides for uniform medical care for dependents of active and retired members of the Army, Navy, Marine Corps, Air Force, Coast Guard, and the commissioned members of the Public Health Service and the Coast and Geodetic Survey in uniformed service facilities. Dependents of deceased members of any of these services, if the member died on active or retired status, are also eligible for medical care. The Act provides for care in civilian hospitals and by civilian physicians of dependents of active duty members, if they are on active duty for more than 30 days.

It is evident that the program for dependents' care resolves itself into two distinct parts—care in uniformed service facilities and care in civilian hospitals. The uniformed service portion of the program will be administered by the Army, Navy, Air Force, and Public Health Service through their Surgeons General, and is a continuation of programs which have been in force on a long uniform basis for many years. These four services will also operate the civilian part of the program in overseas areas except Alaska, Hawaii, and Puerto Rico.

The administration of the civilian part of the program in the United States, Alaska, Hawaii, and Puerto Rico for all six services has been delegated to the Secretary of Defense who has, in turn, delegated this authority to the Secretary of the Army. Further delegation has been to the Chief of Staff, the Deputy Chief of Staff for Logistics, the Surgeon General, and the Executive Director of the program, which position I hold. The Secretary of Defense and the Secretary of Health, Education, and Welfare have issued a directive that delineates the program in detail and is the basis of operation of my office. The essential provisions of the law and the directive are as follows:

**Eligibility.** Those eligible are the wives and children or dependent husbands and children of active duty personnel of the Army, Navy, Marines, Air Force, and Coast Guard and of the commissioned members of the Public Health Service and the Coast and Geodetic Survey when on active duty for more than 30 days.

**Identification.** All of the uniformed services are issuing a new Dependents' Medical Care card. This is to be fully available by 1 July 1957. In the meantime, for those to whom the new card

has not been issued, methods of identification which are in use, plus supplementary information such as driver's license and personal inquiries will have to be utilized

The new identification card is to be known as Dependents' Authorization for Medical Care DD Form No 1173 and will be the same for all of the uniformed services. One card will indicate the names of all dependents. It will be issued for a maximum of two years, or for a shorter time if a serviceman's enlistment or expected tenure of service is for a shorter time at the time of issuance. Each of the uniformed services is responsible for issuing and discontinuing the cards.

**Physician** A physician for this program is "a person who is legally qualified to prescribe and administer all drugs and to perform all surgical procedures." Included are doctors of medicine and doctors of osteopathy who are so licensed by the states and territories.

**Hospital** A hospital means only an institution which is operated in accordance with the laws of the jurisdiction in which it is located pertaining to institutions identified as hospitals is primarily engaged in providing diagnostic and therapeutic facilities for surgical and medical diagnosis, treatment and care of injured and sick persons by or under the supervision of staff physicians or surgeons, and continuously provides 24 hour nursing service by registered graduate nurses. Institutions which are primarily places of rest—those for the aged, nursing homes, convalescent homes and those for treatment of alcoholism or drug addiction—are specifically excluded. Also for the civilian part of the program any facility operated by the Federal Government is excluded, except for emergencies. This excludes the Veterans Administration hospitals from general participation.

**Inpatient Care** The civilian part of the program is essentially for inpatient care. The dependent is entitled to care in semi-private accommodations—two, three, or four beds in a room. Care in a hospital is authorized for diagnosis, treatment of acute medical and surgical conditions, maternity and infant care, dental care that is a necessary adjunct to medical or surgical care (except that restorations are not authorized), acute emotional disturbances where necessary to protect the patient, and contagious diseases. Hospitalization in a civilian facility is authorized for 365 days if necessary, and all necessary services and supplies shall be provided for this period. Hospital care is not authorized to cover treatment of chronic diseases or nervous and mental disorders, elective medical and surgical treatment, domiciliary care, treatments or procedures ordinarily treated in outpatient facilities, or ambulance service.

**Outpatient Care** In general, outpatient care is not authorized. Prenatal and postnatal care is authorized on an outpatient basis for maternity cases. Two visits for infant care as well as immunization during these two visits are authorized. Any therapy, if prescribed while the patient is in the hospital, may be continued on an outpatient basis after discharge from the hospital. In cases of bodily injury, the patient can be cared for as an outpatient at Government expense. Also for bodily injury or surgical operations, a certain amount of pre admission diagnostic tests and services as well as a certain amount of such service following hospital discharge can be had at Government expense.

**Costs to Patient** The patient must pay the first \$25 of the hospital charge or \$1.75 for each day in the hospital, whichever is the greater. If the physician prescribes a private room, the patient must pay 25 per cent of the difference between the private room charge and the weighted average of semiprivate room charge. If the patient elects to have a private room, she must pay all of the difference between private and semiprivate accommodations. If the physician prescribes private nursing service, the patient must pay the first \$100 plus 25 per cent of the additional charges for such service. If the patient desires private nursing service, and this is not prescribed by the physician, she must pay all of the charges for this service. When a patient is treated for a bodily injury and not admitted to a hospital, she must pay the first \$15 of the cost and any charges in excess of \$75 for roentgenographic and laboratory examinations for this treatment. If maternity cases are cared for in the home or office, the patient must pay the first \$15 of the charges. If laboratory and roentgenographic tests are accomplished before admission to a hospital for a surgical procedure under the direction of the attending physician, the patient must pay for all of such charges in excess of \$75, unless additional charges can be fully justified by the attending physician. If tests and laboratory and x-ray procedures are prescribed after discharge from the hospital, the patient must pay all in excess of \$50 of such charges, again unless the physician justifies additional charges. (This does not apply to deep x-ray therapy that is prescribed while the patient is in the hospital. Such therapy can be continued at Government expense after the patient leaves the hospital in accordance with the Schedule of Allowances.)

**Costs to Government** Except for the charges specifically stated to be the responsibility of the patient, the Government will pay the cost. It is emphasized that the dependents' medical care program is a full service plan, and the physician or hospital may not charge the patient any fees other than those which have been specifically designated for the patient to pay.

The progress already achieved by the Office of the Executive Director in the implementation of the program can be summarized in a discussion of hospital and physician costs and the general operation of the program.

**Hospital Costs** The American Hospital Association by resolution of its House of Delegates has recommended that hospitals in states assigned to Blue Cross bill in accordance with Blue Cross rates in effect at the time of submission of a statement. Nonmember hospitals may bill at their standard rates but there is no reason why the Blue Cross cannot try to obtain discounts from these hospitals. Since the basic reason for this lower rate is prompt and complete payment it would appear that hospitals might well allow discounts for the medical care program. The hospitals in those states in which care has been assigned to the insurance industry presumably will bill at their normal rates, but here again it is expected that some discount may be made for prompt and complete payment.

**Physician Costs** Each state medical association was asked to submit a schedule of allowances to be used as a maximum for payment of physicians. The association was asked to name its own Fiscal Administrator. Many states named their own Blue Shield others insurance companies, some decided to handle their own fiscal business. As of 26 November 1956 contracts are in effect in 30 states and territories. 12 additional ones are complete with no differences known to us but ratification by committee, house of delegates or council in these states is pending. This has been accomplished since 24 October by individual negotiations between representatives of each state and a team of Government negotiators. Two days were allowed for each state. Contracts in 10 states are not in effect for various reasons.

**Operation of the Program** Reduced to its most simple terms the operation of the program for hospital care will be somewhat as follows:

- 1 The patient goes to the physician of her choice who sends her to the hospital, performs service, and directs discharge. The physician's bill is submitted on Statement of Services Provided by Civilian Medical Sources DA Form 1863 to the local Blue Shield organization or other fiscal agent who pays the physician directly and consolidates his bill with others; these are forwarded to the Executive Director's office once monthly. The Executive Director certifies the complete amount for payment to local Blue Shield.

- 2 The hospital collects the authorized amount from the patient and submits monthly consolidated vouchers of the balance on the same form to the Executive Director for reimbursement.

3 The physician and hospital programs are both administered by the contractor on a nonprofit basis. In other words, the administrative costs are those actually incurred by the Blue Cross, Blue Shield, medical society or insurance company, and these costs are subject to audit by the Army.

4 The state medical associations are expected to use their grievance and review committees to render advice on questions that may arise as to charges or type of practice. Unusual conditions are reportable to the Executive Director from any source.

5 In those areas where either physician or hospital contracts are not in effect on 7 December, physicians and hospitals can accept patients under the program and forward their bills to the Army commanders for adjudication and payment.

**Fraud.** We are alert to the possibilities of fraudulent acts in this program. They may occur in three general areas. Ineligible persons may pose as dependents. Ineligible hospitals or physicians may submit charges and receive payment. Charges for procedures not accomplished may also be presented for payment. However, methods of identification have been devised. Auditing and inspection procedures will be accomplished. Those who have perpetrated fraud may be subject to prosecution by the Federal Government. Steps will be taken to recover money from individuals or agencies who have defrauded the Government.

**Fee Schedules.** As must be the case with all fee schedules, the one that was sent out does not meet many of the problems which arise. The schedule itself lists some 1,700 items. Approximately 200 common procedures were marked with an asterisk, and the state medical associations were urged to complete a schedule on the items so marked, if they were unable to accomplish a schedule on each item. No way could be devised to recognize in the schedule differences in fees for general practice versus specialty or rural versus urban situations. As a consequence, most of the fee schedules were designed to cover the maximum fees for the specialties. In the field of surgery, many of the procedures are accomplished only by those who have had long training within a specialty. Many procedures, however, are accomplished by general practitioners and doctors of osteopathy as well as by specialists. Specialists' rates for these procedures were, in most cases, quite high. Our office adopted a policy that the fee schedules in each state should represent the normal charges of physicians as a whole, for individuals of an income ranging from \$4,500 to \$5,000 per year. It had been estimated that more than 90 per cent of all of the dependents who seek care under this program will have an average yearly income of not more than \$4,500. All possible information from Blue Shield and other payment plans were used by our negotiators to arrive at a figure for each of the 1,700 items in the schedule.

In many of the states apprehensions were expressed concerning the general philosophy of the Dependents' Medical Care Act. Many persons sincerely fear expansion of this program into other fields. Many fear that the law itself, since it implies a full service coverage, has a tendency to obstruct free communications between the patient and the physician. Some states indicate that their high fee schedules were purposely designed to cover all of these contingencies. On the other hand several states entered into the program in the spirit with which it was approached by Congress and submitted reasonable and acceptable rates, together with a full understanding of the contractual procedures that were necessary insofar as the Government was concerned.

Some of the states have developed elaborate plans for controlling, within their own borders, the amount which will be paid to each physician and will require the physician to accept his normal charges as long as they are within the fee schedules. Many of the states, however, are of the opinion that each physician will charge the maximum rate in the schedule and will be entitled to payment of this amount.

The fee schedules were negotiated by physicians: six Army physicians and one Navy physician represented the Government in the negotiations. Each officer was assigned a state and negotiated privately with the representatives of that state. No attempt was made by the negotiator to establish any national fee schedule. Those matters that were peculiar were taken into consideration in the development of a fee for each item on the schedule.

We have tried to produce an equitable fee schedule with each state, and believe that the state representatives, as a whole, have been conscientious in their endeavors to arrive at fair and equitable schedules.

**Blue Cross and Insurance Companies.** There have been long discussions concerning the coverage of the hospital part of the program by Blue Cross and the insurance industry. It was considered by Congress that in order that comparison of cost to the Government could be made, there should be competition between these two groups.

Contracts with national Blue Cross covering 31 states, the District of Columbia and the Territories of Alaska, Puerto Rico and Hawaii will be in effect on 7 December 1956. Contracts with Mutual Benefit and Health Association will cover 17 states, also going into effect on that date. (Blue Cross states are Washington, Oregon, California, Idaho, Nevada, Arizona, Utah, Montana, Wyoming, Colorado, New Mexico, Michigan, Ohio, Kentucky, Tennessee, Mississippi, Alabama, New York, Pennsylvania, West Virginia, North Carolina, Virginia, Maryland, Delaware.

Massachusetts, Vermont, New Hampshire, New Jersey, Connecticut, Rhode Island, Maine Mutual Benefit and Health Association states are North Dakota, South Dakota, Nebraska, Kansas, Oklahoma, Texas, Minnesota, Iowa, Indiana, Missouri, Arkansas, Louisiana, Wisconsin, Illinois, Georgia, South Carolina, Florida.)

**Doctors of Osteopathy** A real problem has been presented by the definition of a "physician," which as stated before includes doctors of osteopathy in some states. Medical associations of certain states have objected to furnishing information concerning this program to doctors of osteopathy within their states because they consider that this encourages medical practice which in some instances may be substandard.

**State laws vary considerably.** Doctors of osteopathy in some states may, for example, be fully licensed to practice obstetrics but are not legally authorized to prescribe and administer all drugs and to perform all surgical procedures. In some states they fall within the definition of "physician" while in others they do not, being authorized to practice limited medicine only. Efforts are being made through the state medical licensing agencies to determine who is legally entitled to payment under the law as implemented by the directive, and specifically under the definition of "physician."

**Dental Care** Shortly before the joint directive was promulgated, a provision was included for dental care that is a necessary adjunct to medical or surgical treatment rendered to a dependent who is a hospital inpatient in the civilian part of the program. No representation similar to that with the American Medical Association and state medical associations had been accomplished with those representing the dental profession. It was recognized that this was a small program, nevertheless, it was important and some means were necessary to pay the dentists who might render service under the program in its early stage. As an interim measure pending discussion with the dental profession, it was decided to ask the Blue Shield organization, or whatever fiscal agency was serving the state, to accept bills from doctors of dentistry and forward them to the Executive Director's Office in Washington for adjudication and payment.

Veterans Administration schedules have been in effect for many years, and it was considered that those schedules should be used temporarily in adjudication of the charges received. This plan was submitted to the Secretary of the American Dental Association, who felt that the dental profession should be consulted. Arrangements are being made to have a meeting with representatives of the American Dental Association at an early date, in an endeavor to arrive at some better solution to this problem as quickly as possible.

**General Implementation** We are now in the process of setting up the operational features of the program. Cost and statistical analyses and procedures and methods are being devised that will accumulate information for determining the accomplishments of the program and preparing necessary reports. A liaison group composed of a representative of each of the Surgeons General has been established. These representatives will advise the Executive Director of any changes which should be made in the program to assure that it effectively meets the needs of all the uniformed services.

It is our conviction that this is a most important program insofar as morale within the uniformed services is concerned. Every effort will be made to administer it in a manner which will be mutually acceptable to all concerned.

---

#### UNWARRANTED FANCY OR TOMORROW'S EPIDEMIOLOGY?

There is at present no conclusive laboratory evidence that if large enough populations are screened some degree of resistance to any single chemotherapeutic agent cannot be shown for any given *species*. Fortunately, however, at the present time only a few of the potentially resistant pathogenic organisms present clinical problems. It is certainly not a great extrapolation from available evidence to imagine a transfer of resistance in nature from a resistant carrier strain of low pathogenicity to the more highly pathogenic but apparently less mutable stock which was observed in the laboratory. Further investigation alone will reveal whether this is unwarranted fancy or the basis for tomorrow's epidemiology.

# THE FUNCTIONS OF THE NAVAL NEUROPSYCHIATRIC TREATMENT CENTER

JOHN F. McFALLIN, *Captain MC US*

**T**HE ACTUAL establishment and operation of definitive treatment centers for neuropsychiatric patients in the Navy and Marine Corps is of rather recent origin. In fact, the present two treatment centers have been in operation only some seven years. While not a long time, it certainly is of sufficient length for us to assess their worth, measure their accomplishments, perceive their shortcomings, and plan for their improvement.

## BACKGROUND

Prior to 1948, adequate provision for the care of psychotic patients had been made in institutions outside the Navy. From World War I until 1948 the facilities of St. Elizabeths Hospital in Washington, D. C., were traditionally available for our psychotic patients, and from 1942 to 1949 additional facilities for the treatment of psychotic patients were made available at the Public Health Service Hospital at Fort Worth, Tex. Excellent as these facilities were, the expanding role of Navy medicine dictated the need for the establishment of a Navy Neuropsychiatric Treatment Center.

The first such center was planned as an integral part of the U. S. Naval Hospital at Houston, Tex. Hardly had the plans for this been completed when in December 1948, without prior notice, the new U. S. Naval Hospital at Houston was summarily transferred to the Veterans Administration by Executive Order. Coincidentally, at the same time pressure was being brought to bear to have the Navy provide its own facilities for the considerable number of patients which had accumulated both at St. Elizabeths and at Fort Worth, the Bureau of the Budget having denied the Navy the further use of St. Elizabeths Hospital. The immediate problem was great, but, because plans had long since been formulated for the inauguration of neuropsychiatric treatment centers, these were immediately implemented, with the result that not many months later the first of the centers opened at this hospital, and a short while later the west coast center began opera-

tion at the U S Naval Hospital at Mare Island Since April 1950 the west coast center has been at the U S Naval Hospital Oakland Calif Thus only within the past seven years has there been available within the Navy adequate facilities for the definitive treatment of all types of psychiatric disorders

It seems fitting to pause at this point to say a word about the happy relationship between the Navy and St Elizabeths Hospital That large Federal mental hospital of some 7,000 beds supported directly by money from the Congress has been in many ways the model of a state hospital in which capacity it serves for the District of Columbia In 1909 the Surgeon General of the Navy accepted an invitation from the Superintendent of St Elizabeths Hospital to assign naval medical officers to that institution for training in psychiatry This was the initial step toward a recognition of the need for naval medical officers to have postgraduate training in psychiatry In the ensuing years more and more naval medical officers served on the house staff at St Elizabeths and benefited greatly from the guidance of such men as William Alanson White Kempf, and in more recent years Winfred Overholser Many of us who were witnesses to the excellent care our Navy patients received at St Elizabeths up through 1948 saw the passing of this phase of Navy psychiatry with much regret

In order to better orient ourselves with regard to the strategic goals envisioned for our neuropsychiatric treatment centers it will be helpful to go back some years and quote from an address given in 1949 by the then Chief of the Neuropsychiatric Branch of the Bureau of Medicine and Surgery

The program (for these centers) was to lay emphasis on treatment training and research in all categories of neuropsychiatric conditions It is the Surgeon General's wish that the emphasis would not be considered to be on the psychotic with all the negative connotations associated with those conditions (as in other chronic conditions such as chronic tuberculosis) but in providing an outstanding center for the definitive study and treatment of psychiatric cases which require early intensive inpatient procedures The plan is to provide the center with all of the physical and personnel resources to do an outstanding clinical job This would include an expanded staff of psychiatrists clinical psychologists and social workers in addition to an ample number of trained nurses and other ancillary technician personnel

In transferring this program from Houston to the naval hospitals at Philadelphia and Mare Island it was intended that all of the advantages of the center concept would also be transferred with the ultimate aim of concentrating all inpatient psychiatry at Mare Island and Philadelphia so that psychiatrists assigned to other naval hospitals would then be able to devote an increasing amount

of their time to outpatient consultation and treatment with greater emphasis on the preventive aspects of psychiatry. In the actual operation of this plan psychiatrists stationed at other hospitals on the east and west coasts will determine the needs of their psychiatric patients and if, in their judgment, these patients require consideration or treatment other than that which can be given as an outpatient under each psychiatrist's care, the facilities at the two centers would be available for this purpose. It is visualized that these centers will have available excellent clinicians and every possible resource for providing the very best of modern medicine surgery, and psychiatry.<sup>1</sup>

### PRESNT STATUS

The basic plans for each neuropsychiatric treatment center called for a 250-bed unit functioning as an integral part of the general hospital, but with a certain degree of autonomy. Within a short time, additions had to be made to increase the capacity to about 400 beds. I have had the privilege and the experience of having been Chief of Service at both the east and west coast centers, and have been in the rather unique position of attempting to standardize methods of operation and policies in both these institutions. Having spent the past six years in this capacity, I have come to certain conclusions as to the role or function of these centers. But first, I should like to describe what we are presently doing—i.e., our present functions.

The primary responsibility of a psychiatric hospital is to give good treatment and adequate care to its patients. This is being done at our centers in a manner that would be the envy of many of the nation's leading clinics. The fine facilities for the definitive treatment of neuropsychiatric disorders available today for the men and women of the Navy are in sharp contrast to the lack of such facilities even 10 years ago. We seem to have passed the stage of indifference and callousness that in earlier years dictated a policy of rapid disposition when prompt return to duty was not possible. An attitude of hope and helpfulness—a positive therapeutic attitude—is the by-product of this change from an emphasis on disposition of cases to an emphasis on what can be done to help the patient.

Decisions as to fitness for duty are properly relegated to a secondary role, since such decisions are best made only after we have made every reasonable effort to restore the patient to his former state of health. Every military physician has the usual physician's responsibility to his patient, as well as a responsibility to his command, i.e., to the Navy. It may sound like a paradox, but it has been my experience that the latter responsibility, acquired at a later date when the physician dons a uniform, is taken at times somewhat too heavily, to the detriment of the primary responsibility of physician to patient. In our centers,

all the usual forms of psychiatric therapy are available, including electroconvulsive therapy (ECT) insulin coma therapy (ICT) and both specific and nonspecific psychotherapy

**The Training of Psychiatrists** This is a most important function of our centers, and in this regard our east coast center has established an enviable record in providing both long and short courses of instruction in psychiatry for medical officers. This is a continuing operation that had its inception in World War II when, under the direction of Dr Edward A. Strecker, groups of properly selected medical officers were given a three-months' course in basic neuropsychiatry of sufficient intensity to enable them to handle thereafter many of the routine neuropsychiatric problems encountered in the service. It is a singular fact that a high proportion (55 per cent) of those medical officers continued on in the specialty. Of those who did continue, 89 per cent went on to complete their training requirements in subsequent years and of that group over 35 per cent have gone on to Board certification. The last such group convened in the summer of 1952 and following completion of the four months' course, most have continued on for a two-year period as residents in our several hospitals and have gained the experience and maturity that should enable them to be good clinical psychiatrists. At the present time both our centers provide an approved residency training program for two years in psychiatry and for one year in neurology.

**Professional Growth** In the training of residents per se, the emphasis is heavily on the practical aspects of clinical psychiatry with a view toward achieving the maturity that is best gained by the assumption of responsibility for the patient's care. About maturity we see so much striving for it as an end in itself. Just as no one should set out to be happy so no one should strive to become per se a mature adult. Full maturity usually comes as a kind of bonus to experience and to the performance of one's duties in his career and home. An earnest effort is made to overcome present day tendencies of so overloading psychiatric residents with didactic teaching that their opportunities for the direct study of patients are limited.

The attitudes the resident forms during this critical period of his professional growth are as important as the knowledge and skills required of him. It is important that the resident recultivate some of his former interests in logic and philosophy so that he may maintain critical attitudes toward the nature of evidence, its evaluation, what constitutes knowledge, how it is obtained, and what is the difference between an observed fact and an inference. Our residents show a timidity and reluctance to buck current trends and be bold in their thinking. This is related to their fear of ostracism and nonconformity. Our psychoanalytic

institutes are teaching mostly craftsmanship and are not creating an intellectual climate where freedom of thought or the right to dissent too widely is encouraged."

**Administrative Experience** The residency training program in our Navy neuropsychiatric treatment centers is also putting proper emphasis on the role of medical administration in psychiatric hospital treatment. Certain physicians, new to the practice of hospital psychiatry, are frequently unaware of the necessity and the value of medical administration as part of the medical services. There is a real danger that they may become so obsessed with the individual doctor-patient relationship that they may conjure up all sorts of rationalizations to avoid making administrative decisions regarding their own patients. Such may, for instance, result in that unwieldy, unrealistic situation whereby the patient must have two doctors—one a "therapist," the other an "administrator" to control his privileges, et cetera. Like wise, the doctor's failure to appreciate the broader therapeutic role of the hospital often results in a tendency to overuse the purely medical facilities for treatment (like FCT, ICT, et cetera) and to neglect to use all the other resources of the hospital for rehabilitation. In such instances, we often see a failure to use the particular skills of the recreation worker, the social worker, and the occupational therapist, or a blindness to the tremendous opportunities our nurses have to use the techniques of group therapy in their daily contacts with their patients.

A most significant function of our neuropsychiatric centers has been the training of psychiatric aides, or, as they are termed in Navy parlance, neuropsychiatric technicians. To this end, each of the centers conducts a four months' training course, both didactic and practical, in psychiatric nursing and related subjects. The graduates of these schools have made a most significant contribution toward the betterment of patient care in our centers. Both centers have conducted these training courses in the belief that it is the corpsmen who, spending eight hours or more with the patients each day, can influence, either favorably or unfavorably, the patient's prospects for recovery, rehabilitation, and discharge from the hospital. We have just graduated our 39th class of technicians at this hospital.

#### ANALYSIS OF CASE MATERIAL

To more clearly demonstrate the functions of the center in regard to patient care, it would be helpful to analyze the types of patients seen at the center. For this purpose, we have recently completed a study of 200 cases selected at random from a total of 1,691 psychiatric inpatients discharged from this hospital during the year. The general purpose of this study was to attempt to describe the kinds of psychiatric patients which pass through this

service. Only the highlights of this study will be commented on here, since space precludes giving the results in detail and it is planned to publish these later in a separate article. We were, however, interested in certain data so that we might be in a position to measure some of the results of our treatment program.

In evaluating the results of this study two factors both of which tend to operate against each other must be kept in mind. First it must be remembered that service personnel are a selected population in that all had to meet certain minimum physical, educational and mental standards to enter the armed services. In this sense one might safely postulate that service personnel are by and large healthier and better educated than a random sample of the civilian population. Carrying this a step further, it can also be assumed, for these reasons that psychiatrically ill service personnel are, on the whole healthier and better educated than a random sample of patients admitted to civilian state hospitals. An argument could be made that this population would suffer different kinds of mental disorders and differ from the civilian population in other vital respects. Accordingly, perhaps one should be cautious about comparing the results of this study to the populace at large.

Secondly, this hospital is the treatment center for the east coast and as such the great majority of the patients received here are the more serious cases which could not be disposed of at other medical facilities (e. g. ship dispensary local naval hospitals). In other words by the time a patient gets to this hospital he is in most cases at the last stop of the treatment sequence and following discharge from this hospital, is either ready for discharge from the service or return to duty. The previous two factors do not necessarily cancel each other out, however they should be considered in evaluating the following results.

#### Age

The average age of patients admitted was found to be 23 years with a range between 18 and 48. (It is believed that this population is on the whole younger than the patients admitted to civilian state hospitals.)

#### Sex

Ninety three per cent of the patients admitted were male and seven per cent were female. (It is to be expected that in view of the marked preponderance of males in the service a proportionate number of males would be admitted here. Bureau of Naval Personnel statistics report that the proportion of males to females in the entire Navy and Marine Corps is 98.6 to 1.4 per cent.)

### Education

The average (mean) number of years of education completed was 10.7 years, although the most frequently occurring (mode) level which was reached was 12 years or high school graduation. The 1950 census reports that the average number of years of education for the population of the United States in that year was 9.3 years. Thus, the military patient population appears better educated on the average, than the general civilian population.

### Rank

Seven per cent were officers, 25 per cent were rated enlisted personnel, and 68 per cent were nonrated enlisted personnel. (Statistics obtained from the Bureau of Naval Personnel show the following distribution as of May 1954, throughout the Navy and Marine Corps: 10 per cent officers, and 90 per cent enlisted personnel. A statistically significant difference was found in these figures which indicates that officers are less likely to have psychiatric breakdowns than enlisted men. This seems a logical finding in that officers must undergo a much more rigid selection process.)

### Branch of Service

Seventy-four per cent of the patients were in the Navy, 21 per cent in the Marine Corps, and 5 per cent in the Air Force. (The Bureau of Naval Personnel statistics show the following distribution for the entire naval service: 77 per cent in the Navy, and 23 per cent in the Marine Corps. No statistically significant difference was found in this study which would indicate that either Navy or Marine personnel are psychiatrically hospitalized in greater proportion than would be expected from their numerical ratio in the service.)

### Length of Service

The average length of service of patients admitted to the neuro-psychiatric service was 25 months. Twelve per cent of the patients admitted had less than 6 months' service, 22 per cent had less than 1 year's service, and 48 per cent had less than 2 years' service. 94 per cent of all patients (practically all) had less than 3 years' service. This tends to bear out the contention that psychiatric breakdown in the Navy occurs rarely in personnel with more than 3 years' service.

### Family Constellation

Forty-nine per cent of our patient population had parents living together at the time of their admission to the sick list. Accordingly more than half of all the patients (51 per cent) came from homes which were broken for one reason or another. Statistics on the national average of broken homes are not available but it is reasonable to assume that these patient figures are higher. Whether broken homes are a causative factor in mental illness cannot be

answered by this data. It appears to be symptomatic of all forms of social disorganization (e g delinquency and crime as well as mental illness). It is interesting to note that of the 49 per cent who had parents living together there was a note in 18 per cent of these records of considerable parental dissension.

#### Disciplinary Record

Of the patients admitted to this hospital 26.5 per cent had disciplinary charges in their record (i e they were mentioned in the case history and were either in the past or were pending).

#### Source of Admission

Of the patients 72.5 per cent were transferred from another hospital the greatest source of our admissions.

#### Disposition

Thirty nine per cent of the patients were discharged to their homes 32 per cent were discharged to a Veterans Administration hospital 14 per cent were sent back to duty (12 per cent to full duty and 2 per cent to limited duty) 4.5 per cent were sent back to duty for completion of disciplinary action and 7.5 per cent were returned to the marine barracks. (Of this last group 3.5 per cent were returned for discharge 3.0 per cent for orders and earned leave 0.5 per cent to await return to duty and 0.5 per cent for limited duty with discharge recommended.) Though discharge from the service was indicated and effected in 77.5 per cent of all neuropsychiatric patients it is significant that 68 per cent of all patients discharged were well enough to leave the hospital after an average stay of only some 61 days. This speaks well of the efficacy of early treatment for psychiatric disorders.

#### Final Diagnoses

The following categories included patients whose diagnoses were established and also patients whose diagnoses were undetermined (DU). 59 per cent of all cases admitted came in with a diagnosis of psychosis (55 per cent of all cases were schizophrenics) 16.5 per cent of all patients were admitted with a diagnosis of psychoneurosis 9 per cent of all patients were admitted with character and behavior disorders and 15 per cent of all patients were admitted with other than psychiatric diagnoses.

#### Length of Hospitalization

The average length of hospitalization for all patients on this service was 61 days. Patients on the average spent 17 days at another installation immediately prior to admission here. Consequently the total length of hospitalization for the average patient is 84 days.

### Final Diagnoses

**Psychosis**—46 per cent of all patients discharged from this hospital had diagnoses of psychosis. As to be expected, the schizophrenics totaled 43.5 per cent.

**Psychoneurosis**—13.5 per cent of all patients were discharged with diagnoses of psychoneurosis.

**Character and behavior disorders**—36.5 per cent of all patients were discharged with diagnoses of character and behavior disorders. (On admission, only 9 per cent of patients were diagnosed as having character and behavior disorders, which leads us to the conclusion that as common as these are, they are not as readily recognized and are frequently misdiagnosed as either psychosis or neurosis by many medical officers.)

### Treatment

The treatment given patients on this service could only be grouped in rough fashion. For example, psychotherapy could include not only systematic and intensive psychotherapeutic interviews on a regular basis but more casual contacts as well. Because of the ambiguity of the term and the lack of systematic information in the records, there is no breakdown of this category. This should not be interpreted to mean that psychotherapy was not practiced; on the contrary, there was evidence to indicate that it was used rather extensively. In the following categories, the treatment the patient received both prior to admission to this service and while on this service is noted: 15.5 per cent of the patient population received electro-shock treatment (2.5 per cent prior to admission, 13 per cent after admission); 6 per cent received insulin treatment (less than 1 per cent prior to admission, 5.5 per cent after admission); and 80 per cent received nonspecific treatment.

A rather striking phenomenon observed in our hospitals during these past several years (1951 through 1954) has been the rarity of combat neuroses and the infrequency of any type of psychiatric disorder that could be correlated with combat situations. Those of us who saw hundreds of such cases in World War II now are hard pressed to find even one or two cases for teaching purposes.

### THE FUTURE ROLE OF THE CENTERS

The desirability and feasibility of providing definitive psychiatric care for our Navy and Marine Corps patients in the setting of a military hospital has been amply proved and established by the success attendant upon our efforts in both the east and west coast treatment centers during these past seven years. It seems unlikely and inconceivable that the Navy Medical Department will ever take a backward step and delegate this important phase of treatment to a nonmilitary agency or to Federal or State hospitals. The prognosis in psychiatric disorders not only oc-

pends on the availability of adequate treatment facilities, but is greatly influenced by the familiarity of the setting in which treatment is undertaken

Our military patients have a right to the best treatment available and it has always seemed important to me that it be undertaken so far as is possible in our own military hospitals. For the Navy psychotic patient for example to find himself precipitously transferred to a Veterans hospital or a Federal mental hospital brings with it many undesirable connotations and removes a great many of the emotional supports that come from being taken care of by members of his own service family. A parallel example (and one which we should not emulate) is found in those civilian communities that fail to provide adequate psychiatric care for the population. Ideally our larger urban communities (cities or counties) should provide a much larger share of good treatment and not depend so heavily on the state hospitals. Similarly since the Navy can be looked upon as a community in that its personnel have so many common purposes and characteristics it is the Navy which must itself provide the best of treatment for its personnel at the earliest possible moment in the patient's disorder. As this is achieved we find that a decreasing proportion of our patients require transfer to Veterans Administration hospitals near their homes for continued treatment.

Given somewhat more stability of personnel, our centers are capable of expanding their roles in teaching and training. At the U S Naval Hospital at Oakland for example graduate students in psychology and social work from nearby colleges and universities have secured valuable field placements. This is not only a recognition of the diversity of the case material available but also a tribute to the outstanding program of care given our patients. Likewise it would appear feasible to make the facilities of our centers available for the affiliation in psychiatry for students of adjacent nurses training schools. Serious consideration has recently been given to this phase of expanding the Navy's contribution to the betterment of psychiatric care. At the present time the facilities of this hospital are used by the University of Pennsylvania in the placement of nurses undergoing graduate training in psychiatric nursing.

Research is as yet an area largely untouched by our centers. Much can and should be done. In this regard we have an enviable source of follow ups on those patients who are retired, since they are examined at 18-month intervals under current laws.

### UNSOLVED PROBLEMS

One of the unsolved problems is that of providing proper care for those men and women in the service who require only outpatient treatment for psychoneurotic reactions and minor mal-

adjustments. We have seen repeatedly that inpatient care of such patients is as undesirable in military life as it is in civilian life. Too many such cases are being hospitalized, and we are faced with a dilemma in this regard. A possible solution may be the expansion of outpatient facilities at strategic locations such as receiving stations and naval shipyards, but as always, the demand for such facilities always seems to exceed the supply.

It has likewise been amply demonstrated that patients with character and behavior disorders do not for the most part belong in hospitals, but as a result of tradition in the Navy such patients are sent into our hospital neuropsychiatric services for study, evaluation, and disposition. I say study and evaluation, because we have come to learn that many patients with mild or moderate disorders of this type can and, for the most part, should be returned to duty, and as promptly as possible. Most patients of this type will gladly exhibit in the hospital most of their undesirable personality traits, to the point where the medical officer will be too willing to predict that the man could not perform effective duty. Such predictions may only reflect some of his own impatience and hostility, since we have learned in psychiatry during World War II that we should not be too ready to make bad prognoses regarding the abilities of borderline personnel to do effective military duty.

Nonetheless, until such time as we have extramural psychiatric clinics where personnel can be studied and evaluated, we shall probably have to keep to the present system of hospitalization, which results in discharge of a large percentage by medical survey. I am sure that laxity and loose standards in recommending men for discharge in this manner serves only to increase the number of candidates. On the other hand, if we can be more firm in our adherence to standards regarding discharge, if we maintain an attitude of expectation of better military performance, if we can make definite decisions regarding return to duty promptly, we can prevent a great deal of manpower wastage. Just as the man evacuated from combat back to the Zone of the Interior rarely if ever is salvaged for combat, so also the neurotic or psychopath retained in the hospital past a certain critical short period rarely if ever is salvaged for any kind of military duty.

It has been my purpose to outline briefly the present functioning of our two Navy Neuropsychiatric Treatment Centers and to comment briefly on possibilities for the future. I might better term this article a progress report rather than a terminal report, since we continually need to redefine our goals and to modify them in terms of our estimate of the situation and our shifting strategic goals.

\*Instead of reasoning that a patient develops a peptic ulcer *because* of emotional tensions we need to understand that the given patient represents a dynamic aggregate that he is affected by forces which alter his dynamic configuration and that we witness such alterations in the totality of his being and in all of its relations. Similarly instead of conceiving the sick person as having regressed to a lower personality level *because* of his illness we need rather to understand that the interplay of forces which makes the patient sick also and at the same time though possibly in different manifest degrees effects that alteration in personality which we label regressive.

# ENTOMOLOGIC ILLUSTRATION

At the 406th Medical General Laboratory

HUGH L. KREGAN Major MSC USA

**A**LTHOUGH personnel of the Medical Services of the armed services are encouraged to write articles for publication in professional journals, illustration of such articles is often a problem. Most scientists are not skilled artists, and those fortunate individuals who do possess artistic ability can rarely spare the painstaking hours of labor necessary for production of drawings acceptable for publication. A partial answer to this problem for entomologists of the armed services is provided by the taxonomic section of the entomology department of this laboratory. Eight Japanese artists assigned to the section perform a unique service in preparing drawings of medically important arthropods for publication in professional journals or in Army manuals.

This service had its beginning in 1916, when seven artists were employed by the 207th Malaria Survey Detachment to prepare illustrations of mosquitoes of Japan and Korea. The services of these artists passed to the Malaria Survey Section, 35th Station Hospital, in 1950, and to this laboratory in 1951. Projects for which illustrations have been prepared have been directed by both military and civilian entomologists. Among the latter have been prominent Japanese scientists, staff members of the United States National Museum (Smithsonian Institution), and entomologists under contract with the Office of the Surgeon General, Department of the Army.

Since completion of the earlier projects on mosquitoes of Japan and Korea, artists of this group have illustrated monographs on such subjects as mosquitoes of North America and Guam, parasitic mites found on small mammals in Japan and Korea, mite-biculid mites of Japan and Southeast Asia, fleas and black flies of Japan and Korea, Nearctic black flies, *Culicoides* of Japan, Korea, Okinawa, and Formosa, and ixodid ticks of Japan, Korea, and the Ryukyu Islands (figs 1-4).

Figure 1 A mosquito of the genus *Ardomyia*

Prerequisites for employment as an artist in this section have been a degree from a recognized Japanese art school or college plus demonstrated ability. Each newly employed artist is given on the job training for about two months in use of microscopes and the camera lucida drawing techniques required in scientific illustration methods of handling specimens, and structure of medically important arthropods. Four of the original seven artists

## CASE REPORTS

### Sickle Cell-Hemoglobin C Disease

With Splenic Infarction Following High Altitude Ascent

WILLIAM M SWEENEY, *Captain, MC USA*

DONALD A CRIPPEN *Lieutenant MC USA*

JOHN F CHRISTIANSON *Major MC USA*

LANCE B COOK, Jr, *Lieutenant Colonel MC USA*

**A**NALYSES of human hemoglobin by electrophoretic techniques has led to the elucidation of several new clinical syndromes. The initial discovery by Pauling and associates<sup>1</sup> that sickle cell hemoglobin (Hb S) is electrophoretically distinct from the normal adult pigment (Hb A) was followed rapidly by the discovery of other abnormal hemoglobins. In 1950, Itano and Neel<sup>2</sup> reported the discovery of hemoglobin C (Hb C), and since then numerous reports<sup>3-11</sup> on patients with mixed heterozygous combinations of sickle cell and type C hemoglobins have appeared. Chernoff,<sup>12</sup> in projecting the incidence of this syndrome in his clinic to the national population, estimated that approximately 10,000 persons in this country have sickle cell hemoglobin C disease. Prior to the discovery of Hb C, many of these patients were considered to have sickle cell trait or mild and atypical sickle cell anemia.

An additional case of this syndrome is the subject of this report.

#### CASE REPORT

A 34-year-old Negro WAF was first seen on the medical service on 15 April 1954. The patient was admitted with complaints of left abdominal pain which was aggravated by coughing, sneezing, and walking. She also had nausea, vomiting, leg pains, and fever. These symptoms began their onset a few hours after a commercial airline flight from Los Angeles to Albuquerque, N. Mex.

History. The patient gave a history of previous similar attacks beginning at 10 to 16 years of age. Three of these attacks were severe enough to require hospitalization. Numerous milder attacks occurred. Joint pains were prominent symptoms in the previous episodes and were diagnosed as "rheumatism" and rheumatic fever. For the next 2 years the patient felt remarkably well. She engaged in strenuous

at Sandia Hospital, Sandia Base, Albuquerque, N. Mex. Dr. Sweeney is now at the Lederle Laboratories, American Cyanamid Co., Pearl River, N. Y.

are still with the section and are now classified as advisors. In figure 5 four of the artists are shown working at desks which they designed.

*Figure 5 Artists working at desks which they designed.*

Specimens to be illustrated often must be dissected or mounted. Choice of the proper technique is essential if taxonomically important structures are to be clearly shown. Because only a few specimens of many species are available, there is little margin for error or faulty judgment in this work. Material for projects on arthropods from Japan, Korea, and the Ryukyu Islands is usually obtained from preventive medicine units or is collected by an advisor or entomologist assigned to this section. These men also review the Japanese literature and maintain liaison with Japanese medical entomologists.

Illustrations for projects concerning arthropods of areas other than the Far East are accepted upon recommendation of higher authority and approval of the Commanding Officer of the laboratory. In the absence of directed priorities, such projects are accepted on a first come first-served basis. Present commitments will keep the artists occupied until at least September 1958. Speed of accomplishment is not an objective here. The unhurried attention to detail, which results in clear and accurate portrayal, is the best assurance that illustrations produced by members of this section will continue to be of high professional caliber.

## Sickle Cell-Hemoglobin C Disease

With Splenic Infarction Following High Altitude Ascent

DONALD A CRIPPEN *Lieutenant MC USA*

JOHN F CHRISTIANSON *Major MC USA*

LANE B COOK, Jr., *Lieutenant Colonel MC USA*

**A**NALYSES of human hemoglobin by electrophoretic techniques has led to the elucidation of several new clinical syndromes. The initial discovery by Pauling and associates<sup>1</sup> that sickle cell hemoglobin (Hb S) is electrophoretically distinct from the normal adult pigment (Hb A) was followed rapidly by the discovery of other abnormal hemoglobins. In 1950, Itano and Neel<sup>2</sup> reported the discovery of hemoglobin C (Hb C), and since then numerous reports<sup>3-11</sup> on patients with mixed heterozygous combinations of sickle cell and type C hemoglobins have appeared. Chernoff,<sup>12</sup> in projecting the incidence of this syndrome in his clinic to the national population, estimated that approximately 10,000 persons in this country have sickle cell hemoglobin C disease. Prior to the discovery of Hb C, many of these patients were considered to have sickle cell trait or mild and atypical sickle cell anemia.

An additional case of this syndrome is the subject of this report.

### CASE REPORT

A 29 year old Negro WAF was first seen on the medical service on 4 May 1954. The patient was admitted with complaints of left abdominal and flank pain which was aggravated by coughing, sneezing, and walking. She also had nausea, vomiting, leg pains, and fever. These symptoms had their onset a few hours after a commercial airline flight from Kansas City to Albuquerque, N. Mex.

**Post History.** The patient gave a history of previous similar attacks occurring from 10 to 16 years of age. Three of these attacks were severe enough to cause her to be bedridden. Numerous milder attacks occurred. The leg pains were prominent symptoms in the previous episodes and led to the diagnoses of "rheumatism" and rheumatic fever. For the next 10 years the patient felt remarkably well. She engaged in strenuous

---

From U. S. Army Hospital, Sandia Base, Albuquerque, N. Mex. Dr. Sweeney is now at Research Division, Lederle Laboratories, American Cyanamid Co., Pearl River, N. Y.

athletic activity enlisted in the WAF and completed basic training. In 1952 she was transferred to Albuquerque and frequent attacks of left abdominal and flank pain again occurred. When hematuria complicated one of these episodes she was examined at a general hospital where the consultant urologist was unable to demonstrate organic genitourinary disease. However noting sickling on a blood smear he suggested that the hematuria could have been a result of sickle-cell disease.

**Family History.** The patient's mother died of cancer; her father is living. One male sibling died at age 14 from hemorrhage following an appendectomy and another brother died at age 7 of a "heart attack." The patient recalled that as a child she and other members of her family were repeatedly examined for the presence of sickle-cell disease but she was unaware that a definite diagnosis ever had been made.

**Physical Examination.** Examination revealed an acutely ill young Negro woman moderately dehydrated with a temperature of 100 F. There was tenderness to palpation over the left upper abdominal quadrant; the spleen was palpable firm and moderately tender. Slight ankle edema was noted and there was marked tenderness to palpation over the anterior surface of both tibiae. The remainder of the physical examination was normal.

**Laboratory Findings.** Hematologic findings on admission are summarized in table 1. Urinalysis and liver function tests were normal. Roentgenograms of the chest, skull, tibiae, and fibulae were normal. Electrocardiographic findings were within normal limits. Paper electrophoretic study of the patient's hemoglobin revealed mobilities which corresponded to those of S and C hemoglobins present in approximately equal amounts.

TABLE 1 Hematologic data on admission

Red blood cell count	3,550,000 per $\mu$ l
White blood cell count	14,400 per $\mu$ l
Hemoglobin	9.5 gram per 100 ml
Reticulocytes	2.2%
Sickling of red blood cells	present
Target cells	numerous
Platelet count	46,000
Sedimentation rate	4 mm/hr
Osmotic fragility	0.33 to 0.15%
Serum bilirubin, total	2.8 mg per 100 ml
Bone marrow	erythroid hyperplasia

**Subsequent Course.** On symptomatic therapy the patient improved. The anemia and thrombocytopenia which were present on admission gradually disappeared. She was then sent on temporary duty to an installation in New York State where she was in excellent health. In August 1954 the

patient returned by train to New Mexico. She traveled for two days with no difficulty but on reaching the higher altitude of Colorado she developed nausea, vomiting, and left upper quadrant pain. The symptoms progressed in severity and led to her hospitalization when she arrived in Albuquerque. Findings were similar to her first hospitalization. Again the patient gradually improved and she was discharged in November 1954, with a recommendation that she be stationed at a low altitude. This was done and follow up five months later revealed the patient to be entirely asymptomatic.

### DISCUSSION

According to the concept originally proposed by Neel,<sup>11</sup> sickle cell Hb C disease is a heterozygous disease with one parent contributing the gene for sickling and the other contributing the Hb C gene. Sickle cell anemia is the homozygous condition in which a gene for sickling is inherited from each parent. Table 2 summarizes some important differences among the three common sickle cell abnormalities: sickle cell trait, sickle cell anemia, and sickle cell Hb C disease.

TABLE 2 *Comparison of the three common sickle cell abnormalities*

	Sickle-cell trait	Sickle cell Hb C disease	Sickle-cell anemia
Hemoglobin pattern	A + S	S + C	S + F
Incidence (American Negroes)	1/12	1/5,000	1/600
Sickling	present	present	present
Target cells	0-5%	20-85%	5-30%
Anemia	-	- to ++	+++
Crises	-	- to ++	+++
Splenomegaly	-	+	-(adults)
Osmotic fragility	normal	decreased	decreased

Widespread use of electrophoretic techniques has led to the discovery of other abnormal hemoglobins. These have been designated as hemoglobins D, E, G, H, and I. Fetal hemoglobin (Hb F), which is not under the genetic control of the same set of allelic genes that determines Hb A, may persist into adulthood in patients with thalassemia, sickle cell anemia, and other hemolytic anemias.

Sickle cell Hb D disease<sup>12</sup> and sickle cell Hb G disease<sup>13</sup> have also been reported, but evidently are rare conditions. Combination of sickle cell hemoglobin with the remaining abnormal hemoglobins is theoretically possible but has not as yet been reported.

Hb C may exist alone (homozygous Hb C disease) or in combination with normal hemoglobin (Hb C trait). Sickling of erythrocytes is absent but target cell formation is a prominent feature of these conditions.

A definite diagnosis of sickle cell Hb C disease is possible only by electrophoretic analysis of the patient's hemoglobin. However, clinical suspicion should be aroused by the observation of a Negro patient who exhibits symptoms suggestive of "atypical" sickle cell anemia with splenomegaly, sickling, and numerous target cells in the peripheral blood smear.

Although the clinical course of sickle cell Hb C disease is usually milder than that of sickle cell anemia, the disease cannot be regarded as benign. Hematuria, crises with anemia, and splenic infarction resultant from aerial flight, as illustrated in this case history, are common complications. In an analysis of 16 persons with sickle cell Hb C disease, Smith and Conley<sup>10</sup> observed roentgenographic evidence of aseptic necrosis of the femoral or humeral heads in five. The same authors reported severe exacerbations of symptoms during pregnancy and two post partum deaths from hemorrhage. Thrombocytopenia, as observed in our patient, has not been a characteristic finding in the reported cases of this syndrome.

Infarction of the spleen during airplane flight has been observed in six cases of electrophoretically proven sickle cell Hb C disease.<sup>16-18</sup> A clinically diagnosed infarct occurred in our patient after a commercial airline flight. The occurrence of a similar episode in this patient after high altitude land ascent by train (to approximately 5 000 feet above sea level) illustrates the apparent extreme sensitivity of these persons to minor degrees of hypoxia.

#### SUMMARY AND CONCLUSIONS

A case of sickle cell hemoglobin C disease is presented, together with a brief review of the clinical, hematologic, and electrophoretic findings in this syndrome.

Observation of a Negro patient with symptoms of "atypical" sickle cell anemia, splenomegaly, sickling, and numerous target cells in peripheral blood smear should suggest the possibility of sickle cell hemoglobin C disease. The diagnosis can be confirmed by the relatively simple technic of paper electrophoresis.

---

**ACKNOWLEDGMENT** The authors are indebted to William P. Jencks, First Lieutenant MC USAF, Walter Reed Army Institute of Research, for the electrophoretic studies.

with a depression of 0.3 cm below the adjacent cortical surface. Attached firmly to such scars were large quantities of perirenal fat and fibrous tissue. On section both kidneys appeared to be atrophic and the parenchyma was greatly thinned. The renal pyramids were flattened and the calyces were greatly dilated. The cortex measured a maximum of 3 mm in thickness and, in areas of extreme thinning, the corticomedullary junction was indiscernible. Both ureters were dilated, tortuous, and elongated.

The surface vessels of the brain were conspicuous and engorged. The leptomeninges were slightly thickened by irregular deposits of grayish white opaque tissue.

*Histological findings.* In both lungs multiple clusters of alveoli were filled by an exudate of polymorphonuclear leukocytes, large mononuclear cells, serum, and a few extravasated erythrocytes. The blood vessels were moderately engorged. Stainable fat was present within small arteries and within alveolar capillaries (fig. 1) and occasionally it was demonstrable within the alveolar lumen. Using Kent's<sup>1</sup> classification this extent of fat embolism was considered approximately 2 plus. Occasionally, fat was found within the cytoplasm of macrophages.

Figure 1 Frozen section of lung showing fat (black) in the lumina of a small artery in the center and a capillary at the margin of the photograph (Oil red O stain,  $\times 350$ )

Sections from the myocardium showed slight fragmentation, vascular engorgement to a slight degree, and occasional fat vacuoles within capillaries. Nearly all of the hepatic cells contained large intracytoplasmic fat vacuoles. A few lobules showed central collections of polymorphonuclear leukocytes. Similar inflammatory cells were noted in the portal areas. Fatty cysts were present (fig. 2).

Figure 2. Section of liver showing fatty metamorphosis and fatty cyst formation. (Hematoxylin and eosin stain,  $\times 400$ )

Sections from both kidneys showed irregular areas in which there was a marked increase in interstitial fibrous connective tissue, infiltration by lymphocytes, and replacement of many glomeruli by balls of partially hyalinized fibrous connective tissue. Colloid casts were seen in some of the tubules. Blood vessel walls were moderately thickened due to fibrous tissue proliferation. Occasional glomeruli showed slight pericapsular fibrosis. Stainable fat was present within many glomerular capillary loops and occasionally within small arteries (figs. 3 and 4).

Toxicological examination showed 3.15 mg of ethyl alcohol per gram of brain tissue, or 0.315 per cent. The gastric content showed 10.2 mg of ethyl alcohol per ml of gastric content, or 2 ml in 150 ml of specimen. Gettler and Tiber<sup>2</sup> gave 0.27 to 0.51 per cent as the lethal range of ethanol in brain tissue.

Figure 3 Frozen section of kidney. Fat emboli (black) plug the capillary loops beneath the glomerular capsule on the right (Oil red O stain  $\times 350$ )

#### DISCUSSION

The significance of fat emboli is still debated. Kent studied 53 nondiabetic and nontraumatized adult patients who had come to autopsy. He found a very occasional fat embolus in the lungs of 10 cases. These were multiple in one case. In 53 diabetics, fat emboli were found in the lungs of 24, rare in 19, in more than one location in 2, and in almost every low power microscopic field in 3. He believed that the emboli were of no clinical significance in either group.

Hedren<sup>3</sup> is said to have reported a fatal pulmonary fat embolism in one diabetic patient. Durlacher and associates<sup>4</sup> studied 25 cases of sudden death in persons with alcoholic fatty liver. Five of the deaths were attributed to massive pulmonary fat embolism. Fat emboli in the lungs of three other patients were not thought to be the cause of death. Graham,<sup>5</sup> in reporting a group of young adults with fatty liver and sudden death, did not mention the presence of fat emboli. MacMahon and Weiss<sup>6</sup> found microscopic fat emboli in the pulmonary artery of a patient who died from carbon tetrachloride poisoning.

Sections from the myocardium showed slight fragmentation vascular engorgement to a slight degree and occasional fat vacuoles within capillaries. Nearly all of the hepatic cells contained large intracytoplasmic fat vacuoles. A few lobules showed central collections of polymorphonuclear leukocytes. Similar inflammatory cells were noted in the portal areas. Fatty cysts were present (fig. 2).

Figure 2. Section of liver showing fatty metamorphosis and fatty cyst formation. (Hematoxylin and eosin stain,  $\times 400$ )

Sections from both kidneys showed irregular areas in which there was a marked increase in interstitial fibrous connective tissue infiltration by lymphocytes and replacement of many glomeruli by balls of partially hyalinized fibrous connective tissue. Colloid casts were seen in some of the tubules. Blood vessel walls were moderately thickened due to fibrous tissue proliferation. Occasional glomeruli showed slight pericapsular fibrosis. Stainable fat was present within many glomerular capillary loops and occasionally within small arteries (figs. 3 and 4).

Toxicological examination showed 3.15 mg of ethyl alcohol per gram of brain tissue or 0.315 per cent. The gastric content showed 10.2 mg of ethyl alcohol per ml of gastric content or 2 ml in 150 ml of specimen. Gettler and Tiber<sup>2</sup> gave 0.27 to 0.51 per cent as the lethal range of ethanol in brain tissue.

They did not consider the possibility of repeated fat embolization from the liver to the kidneys. However, experimental production of fat emboli in choline-deficient rats has resulted in lesions which simulate both the focal and diffuse types of lesions seen in the Kimmelstiel-Wilson syndrome. The liver was considered the probable source of the emboli.<sup>11</sup>

The detection of fat emboli requires foresight of the pathologist, and special handling of the tissue at the time of autopsy. It is to be expected that if it is more frequently sought the lesion will be encountered more often and its importance more accurately defined.

### SUMMARY

The autopsy findings in a man who died suddenly, apparently of acute ethyl alcohol intoxication, included marked fatty metamorphosis of the liver with fatty cyst formation. Microscopic fat emboli were found in the renal, pulmonary, cardiac, and cerebral tissues. These emboli were not thought to have been an important factor in the sudden death of this patient, but do illustrate a probable mechanism by which the fatty liver may produce changes in the kidneys and possibly other viscera.

*Figure 4 Frozen section of kidney Fat emboli (black) plug the majority of the capillaries of the single glomerulus shown. (Oil red O stain,  $\times 500$ )*

The pathogenesis of the lesion has been well worked out in animals and in man. In working with choline-deficient rats Hartroft<sup>7</sup> and Hartroft and Ridout<sup>8</sup> showed that the liver cells become engorged with fat, the cell wall ruptures, and neighboring cells coalesce to form fatty cysts. These in turn may rupture and discharge globules of fat into the hepatic sinusoids, whence they are carried to lungs, brain, kidneys, and heart. A similar course of events is known to occur in man, but significant embolization of fat apparently is rare.

In the case reported above, we do not feel justified in attributing death to multiple fat emboli. Acute alcohol poisoning was present with lethal tissue concentrations. The fatty liver was certainly the source of the many fat emboli to lungs, kidneys, myocardium, and brain. Fatty liver is a common accompaniment of chronic alcoholism, but may occur with other conditions.<sup>9</sup> The hazard of repeated small emboli to vital organs is probably more important than the risk of significant sudden massive pulmonary embolization, because the latter is so uncommon. Patek, Segal, and Bevans<sup>10</sup> found intercapillary glomerulonephritis to be much more frequent in cirrhotic patients than in the general population.

# Epidural Intracranial Abscess

ROBERT P KOENIG *Captain, USAF (MC)*  
THOMAS K CRAIGMILE *Captain USAF (MC)*

**E**PIDURAL intracranial abscess uncomplicated by other intracranial infection and not associated with osteomyelitis of the skull is uncommon.<sup>1-7</sup> The case reported here is the only one seen at this hospital in the five years it has been in operation, during which period the yearly patient admission rate averaged 20 000.

## CASE REPORT

The patient an 18 year old airman was in good health until 15 June 1955 when he noted the onset of mild right frontal headache. No other symptoms of sinusitis were present. Several physical and neurologic examinations apparently were negative and the patient was treated as an outpatient with mild medication for headache. About two weeks later however he noted the onset of a low grade fever for the first time and a considerable increase in the severity of his headache. That night the patient became acutely ill. His temperature on admission to the local medical facility was over 104°F and he was manic. Neurologic examination revealed no localizing findings. He did not have a stiff neck. Antipyretic therapy and 180 mg (300 000 units) of penicillin were given every four hours.

The following day a spinal tap revealed a pressure of over 300 mm of water. Examination of the spinal fluid revealed 109 lymphocytes per 100 ml, sugar 91 mg per 100 ml and total protein 22 mg per 100 ml. Smear and culture studies were negative as was a blood culture. His white blood cell count was 12 250 per  $\mu$ l with 73 per cent polymorphonuclear neutrophil cells. The blood sedimentation rate was 34 mm/hr. The remaining laboratory studies were within normal limits.

Following the spinal tap the patient noted rather dramatic relief from his headache. Streptomycin sulfate and sulfadiazine (dosage unrecorded) were added to the penicillin he was already receiving. Within 48 hours the patient was asymptomatic. Antibiotic therapy was continued for a total of seven days and then discontinued. Because he remained symptom free and a repeat spinal fluid examination was entirely negative he was discharged on the eleventh hospital day.

---

From U S Air Force Hospital, Sampson Air Force Base, New York City. Received at 475th U S Air Force Laboratory, Minneapolis-St Paul International Airport, Minneapolis, Minn.

The patient remained well until three weeks later when a recurrence of the right frontal headache developed. Neurologic examination on readmission was said to be negative, but the patient was running a low grade fever. Spinal fluid study revealed an initial pressure of 170 mm of water. Ten lymphocytes per 100 ml were present and smear and culture studies again were negative. No medication was given during this hospitalization. Despite a persistent lack of local neurologic findings, the headache and low grade fever persisted and manometric study revealed a steadily increasing spinal fluid pressure up to 690 mm of water.

On 10 September 1955 the patient was transferred to the department of neurology at this hospital where the previously mentioned findings were verified. Agglutination studies, roentgenograms of the skull, and numerous electroencephalograms were normal. Spinal fluid dynamics revealed an initial pressure of 460 and a closing pressure of 100 mm of water. Unfortunately, the laboratory report of studies on this fluid was lost.

Repeat neurologic examinations eventually disclosed a slight but definite papilledema although localizing signs remained absent. A tentative diagnosis of brain tumor or brain abscess was made and the patient was transferred to neurosurgery. A right carotid percutaneous angiogram failed to reveal any definite abnormality (fig. 1). This was followed by ventriculography which demonstrated ventricular displacement to the left as seen in figure 2. A right frontal craniotomy was immediately performed. When the lowermost burr hole situated just above the supraorbital ridge near the mid line, passed through the inner table, thick creamy yellow pus welled up out of the wound. Culture later produced a pure growth of a nonhemolytic coagulase negative staphylococcus organism. An estimated 100 ml of pus was flushed from the wound. A frontal flap was turned and a large well-organized abscess capsule was seen overlying the dura of the frontal pole. A dome-like elevation of the dura was opened but normal appearing brain was encountered. This dural defect was closed after liquid bacitracin was instilled subdurally. A considerable amount of bone in the supraorbital area was rongeuried away and a generous portion of the bone flap was sawed free and discarded. The epidural space was thoroughly debrided and irrigated. Bacitracin solution was instilled therein and the wound was closed. A small rubber drain was left in the epidural space, being exteriorized through a small incision in the scalp flap.

The patient tolerated the procedure very well. He had been given 600 mg (1 000 000 units) of penicillin and 1 gram of streptomycin sulfate at the time of the operation. This was later changed to chlorotetracycline hydrochloride (aureomycin) when sensitivity studies were reported on the staphylococcus organism.

The drain was removed after five days but rather profuse drainage persisted for several weeks. Antibiotic therapy was altered to Chloro-

*Figure 1 Angiogram which failed to definitely reveal the presence of the extradural frontal abscess mass.*

mycetin (brand of chloramphenicol) in accordance with later serum levels. Antibiotic therapy was continued for five weeks.

*Figure 2 Ventriculogram showing ventricular displacement to the left.*

The patient has remained symptom free to date (10 February 1956). Careful study of the bone fragments by the pathology department did not reveal evidence of osteomyelitis.

#### SUMMARY AND CONCLUSIONS

Epidual intracranial abscess without other intracranial infection and without osteomyelitis of the skull is uncommon. In addition, the above reported instance of this disease presented two features which are instructive. It illustrates the difficulty of early diagnosis of epidural brain abscess (1) when there is no overt evidence of a primary source of infection and (2) when the development of intracranial complications of ear and sinus infection is masked and localized by antibiotic therapy.<sup>1,2</sup> The failure to develop even a minimal amount of osteomyelitis of the

skull was probably due to early antibiotic therapy. As is usual in epidural abscesses, a micrococcus (staphylococcus) organism was isolated.

#### PSYCHOTHERAPY

There was an Army doctor I once knew who had discovered and practised a very useful therapy for malingerers. He would listen attentively to their imagined symptoms, then examine with an air of increasing gravity some unexpected portion of their anatomy. He was, if I remember rightly, an Irish doctor. He would tell the man to return to duty and report again in three days' time. For if you are no better, I'm afraid there's nothing for it but an operation. And he would lightly describe an operation compared with which the martyrdom of a Christian saint was no more than a summer cold.

## Tietze's Syndrome

REYNOLD E. KLAGGS Jr. *Captain USAF (MC)*

**T** IETZE'S syndrome is a nonsuppurative, nonspecific, painful, benign swelling of the costochondral or the sternoclavicular junctions. About 30 years ago it was originally described in the German literature.<sup>1</sup> It seems justifiable to include this condition in the differential diagnosis of chest pain.

As is noted in the literature, this particular syndrome usually occurs in persons between the ages of 18 and 40 years, but it has been reported in individuals as old as 60 years. In the service, both military personnel and their dependents often are seen at the hospital or clinic with the complaint of "pain in the chest." Due to the now recognized fact that cardiovascular changes can occur at any early age and that the public is much more conscious of this, it is incumbent upon physicians to differentiate the serious from the benign conditions that produce chest pain. It therefore seems timely to report a case of Tietze's syndrome observed at this hospital.

### CASE REPORT

A 19-year-old married white woman was first seen in the dependent's clinic on 10 February 1955 because of persistent pain in the upper right chest. The patient stated that she had been perfectly well up until about two months earlier at which time she noted an enlargement in the area that anatomically would be considered the right sternoclavicular joint. For the past month the area had been extremely painful. About one week before she came to the clinic the pain increased in severity. There was no history of falls, blows to the chest, heavy lifting, or wrenching or pulling of the right shoulder girdle. The onset was insidious; the patient first noting tenderness one morning when rolling over on her right side in bed. Upon examining herself in the mirror she saw a slight lump in this area. It was more painful on arising in the morning and on moving the right shoulder girdle and during the day and toward evening the soreness would improve slightly. She used hot Epsom salts compresses to no avail. She had taken no medication orally before coming to the clinic.

skull was probably due to early antibiotic therapy. As is usual in epidural abscesses, a micrococcus (staphylococcus) organism was isolated.

# Tietze's Syndrome

REYNOLD F. FLAHERTY, Jr. *Captain USAF (MC)*

**T** IETZE'S syndrome is a nonsuppurative, nonspecific, painful, benign swelling of the costochondral or the sternoclavicular junctions. About 30 years ago it was originally described in the German literature.<sup>1</sup> It seems justifiable to include this condition in the differential diagnosis of chest pain.

As is noted in the literature, this particular syndrome usually occurs in persons between the ages of 16 and 40 years, but it has been reported in individuals as old as 60 years. In the service, both military personnel and their dependents often are seen at the hospital or clinic with the complaint of "pain in the chest." Due to the now recognized fact that cardiovascular changes can occur at any early age and that the public is much more conscious of this, it is incumbent upon physicians to differentiate the serious from the benign conditions that produce chest pain. It therefore seems timely to report a case of Tietze's syndrome observed at this hospital.

## CASE REPORT

A 19-year-old married white woman was first seen in the dependent's clinic on 10 February 1955 because of persistent pain in the upper right chest. The patient stated that she had been perfectly well up until about two months earlier at which time she noted an enlargement in the area that anatomically would be considered the right sternoclavicular joint. For the past month the area had been extremely painful. About one week before she came to the clinic the pain increased in severity. There was no history of falls, blows to the chest, heavy lifting or wrenching or pulling of the right shoulder girdle. The onset was insidious, the patient first noting tenderness one morning when rolling over on her right side in bed. Upon examining herself in the mirror she saw a slight lump in this area. It was more painful on arising in the morning and on moving the right shoulder girdle, and during the day and toward evening the soreness would improve slightly. She used hot Epsom salts compresses, to no avail. She had taken no medication orally before coming to the clinic.

---

From U. S. Air Force Hospital, Hunter Air Force Base, Ga.

Her past history was noncontributory. She had the usual childhood diseases except mumps. She had had no operations and had borne no children. She had always been in excellent health. There was no family history of tuberculosis, diabetes mellitus, or other familial diseases.

Physical examination on admission revealed a well-developed, well-nourished white woman in no acute distress. Temperature was 98.6°F, pulse rate 88/min, respiration 20/min, blood pressure 120/74 mm Hg. There was a firm, slightly tender, bulbous mass at the right sternoclavicular joint. The patient was able to move the right shoulder girdle in all directions without limitation. The mass was about 2 by 3 cm, smooth, and slightly raised. It was not movable, and there was no crepitation. There was no evidence of dislocation of the right shoulder girdle or sternoclavicular joint. The lungs were clear to auscultation and percussion. The heart tones were of good quality, sinus rhythm was regular, and no shocks, thrills, murmurs, or accentuation were noted. The remainder of the physical examination was within normal limits.

The laboratory studies revealed a red blood cell count of 4,500,000/ $\mu$ l, hemoglobin 15 g/100 ml, and white blood cell count 10,500/ $\mu$ l with 92 per cent neutrophils. Sedimentation rate was 20 mm per hour (Wintrobe). The serologic test was negative. Blood urea nitrogen was 15 mg/100 ml, and total protein was 7.5 g/100 ml (albumin 4.5, globulin 3.0). Urinalysis was negative for sugar and bile, and the microscopic examination was negative. Prothrombin concentration was 100 per cent of normal, fasting blood sugar 110 mg/100 ml, calcium 9.5 mg/100 ml, uric acid 3 mg/100 ml, cholesterol 200 mg/100 ml, and inorganic phosphorus 4 mg/100 ml. Chlorides were 104 meq/l, sodium 140 meq/l, and potassium 4.5 meq/l. Liver function tests were within normal range. The electrocardiogram, consisting of all 12 leads, was reported as being within normal range. Roentgenograms of the chest and the right sternoclavicular area were within normal limits.

The patient was given no medication. During the next few weeks the lesion decreased in size, and on the next to last visit there was a very slight residual tenderness upon deep pressure. On her last visit, about six weeks after the first, there was no discomfort either on digital pressure or as a result of right shoulder girdle motion. Physical examination was entirely negative, and there was no evidence that there had been a lesion in this area.

### DISCUSSION

The patient with Tietze's syndrome usually complains of a painful sensation in the chest area. The discomfort may be vague, nondescript, and diffuse or fairly well localized. The patient may describe it as a heavy weight that seems to be pushing

in on the chest, or it may be described as only a soreness which is present on deep respiration. The intensity of the pain may be more severe at different times of the day. Several factors, including anxiety, weather, type of work, infection, et cetera, apparently aggravate the condition.

Tietze's syndrome should be considered in the evaluation of chest pain because of the similarity of its symptoms to those of many different organic diseases. The differential diagnosis should include such serious conditions as carcinoma of the lung or breast and any of the serious cardiac conditions that might mimic the pain of Tietze's syndrome. Truism in any form should be ruled out by history, physical examination, and roentgenograms.

Hodgkin's disease should be considered in the differential diagnosis because it may produce sternal swelling at the level of the second and third intercostal spaces as a result of involvement of the nodes along the course of the internal mammary artery.<sup>2</sup> However, in Hodgkin's disease there is no sternal tenderness, in contrast to the painful condition found in Tietze's syndrome. Osteochondritis can be differentiated radiologically,<sup>3</sup> mumps with presternal edema can be differentiated for it is not tender and usually lasts only five days.<sup>4</sup> All of these characteristics are quite different from those found in the swelling of Tietze's syndrome.

Following the exclusion of a serious lesion two other conditions which should be thought of in relation to chest pain from a superficial cause are slipping rib<sup>5</sup> and nerve nipping at the intercostal margin. These can generally be differentiated by careful physical examination and should cause no confusion.

Reports of the microscopic characteristics of the lesion are inconsistent and indefinite. Biopsy specimens may show thickening of the perichondrium, muscle fasciculi, and/or ligaments surrounding the costochondral junction, and at times an enlargement of cartilage around the joint involved. All of the reports indicate an absence of inflammatory change in cartilage and surrounding soft tissue. It is believed that all of the reported histologic changes could be normal variations of the costal cartilage.

On examination the findings are limited to the areas about the involved costochondral or sternoclavicular junctions. As was noted in this case report there is usually a tender, fusiform, or bulbous swelling involving the soft tissue, cartilage, or bone. The skin above the involved area is not changed or discolored, and there is no crepitation nor pitting edema. Radiologic findings of significance are rarely noted.

The course of the disease varies according to the reports \* It may be long and varied with remissions and exacerbations or it may be quite short a matter of days or weeks

The treatment is entirely symptomatic and consists of local application of heat, the use of salicylates for pain, and if necessary infiltration with a local anesthetic The patient should be reassured that the condition is benign that it will heal in time, and that no residual damage is anticipated

This case report is typical of those recorded in the literature The onset was insidious, and there was no apparent cause of the lesion No treatment was given and after about four months the patient was asymptomatic and physical examination was normal

### SUMMARY

A case of nonspecific painful swelling of the sternoclavicular joint has been presented as an example of Tietze's syndrome The cause of this condition is unknown and it has a variable and often prolonged and fluctuating course Since this syndrome is not believed to be rare, it should be considered along with more serious disorders in the differential diagnosis of chest pain It is of particular importance that these patients be reassured of the benign nature of the disorder

## Departments

### A MESSAGE FROM THE A M A

With the 85th Congress convening this month, the American Medical Association will continue to be kept busy following congressional activity, particularly in areas concerning medicine and public health. There has been an increase in the total measures introduced and laws enacted in the last two Congresses. Medical and health bills, as well as enacted laws, likewise increased. The following table indicates the extent of these activities:

Legislation	83d Congress (1953-1954)	84th Congress (1955-1956)	Increase (Per cent)
Measures introduced			
Total	16,372	19,039	16
Concerning medicine	407	571	40
Public laws enacted			
Total	781	1,028	31
Concerning medicine	20	26	30

When the 84th Congress completed its second and final session on 26 July 1956, over 19,000 measures had been introduced. The Association analyzed and closely followed 571 of these bills which had medical or health implications. Most of the 26 medical measures which became law were supported by the Association by oral or written statements presented to the committees or members of Congress.

The Association opposed two measures which became public laws in 1956. One amended the Social Security Act by establishing a disability cash benefit program for persons between ages 50 and 65; the other authorized medical corps commissions for osteopaths in the armed services, but on a permissive basis.

There were six military medical laws enacted by the 84th Congress. Two were enacted in the first session and four in the second session. It is believed that medical officers will be interested in the following general summary of these laws.

Public Law 118, 30 June 1955, extended the Doctor Draft Act for two years until 1 July 1957, which the Defense Department

From the Council on National Defense of the American Medical Association. The views and opinions expressed are not necessarily those of the Department of Defense.  
—Editor

claimed was essential to get enough physicians to maintain high standards of medical care for military personnel. It also extended for four years, the \$100 a month equalization pay for physicians and others on active military duty. Reflecting some of the objections of the American Medical Association in opposing an extension of the Doctor Draft Act, it amended the law by (a) lowering the age limit for call up of special registrants from 51 to 46 years of age, and (b) exempting from induction special registrants over the age of 35 who had previously applied for commissions as medical or dental officers in one of the armed services if they had been rejected solely on the basis of a physical disability.

The Department of Defense has indicated to the Association that it will not seek an extension of the Doctor Draft. Legislation has been proposed to amend the basic Universal Military Training and Service Act to provide for the selective call up of physicians along with others who have general draft liability. Under the present basic draft act physicians who have been deferred beyond age 26 to complete their medical education are liable for service up to age 35. The proposed legislation is designed to provide for an orderly call up of these deferred physicians.

Public Law 294 9 August 1955 authorized reserve commissions for the first time for male nurses in the armed services. The A M A took no position on this legislation.

Public Law 402 27 April 1956 authorizes the President to make the U S Public Health Service a military branch in time of emergency involving the national defense. Prior to this such status was permissible in time of war but not in time of emergency. The Public Health Service considered this change necessary to discharge adequately its new civil defense responsibilities. After the Surgeon General of the Public Health Service assured the Association that the proposed legislation would not be used for the purpose of placing calls for civilian physicians with the Selective Service System in time of national emergency, the American Medical Association then supported the measure.

Public Law 497 30 April 1956 was designed to increase the career attractiveness of military medicine. In addition to the \$100 a month equalization pay medical officers under the law receive an additional increase in pay of \$50 at the end of 2 years service, another \$50 at the end of 6 years service and another \$50 at the completion of 10 years service. The original version of the bill provided for the first pay increase at the end of 3 years. As finally enacted it included the A M A recommendation for an increase at the end of 2 years. Another A M A recommendation not included in the law called for an increase

in the amount of special pay to more nearly equalize military salaries with the salaries offered physicians of equal training and experience as civilian employees of the government.

Other features of the law provide for longevity pay credit for the 1 postgraduate year spent in medical schools and for the 1 year spent in medical internship, as well as upgrading of officers now on the active list to reflect the 1 year increase of constructive service credit.

Public Law 569, 7 June 1956, authorizes a uniform program of medical care for members of the uniformed services and their dependents. The Dependents' Medical Care Act authorizes medical care of all military dependents in military facilities subject to availability of space facilities, and capabilities of staff. The Secretary of Defense is authorized to arrange for medical inpatient care for spouses and children of active duty personnel in civilian medical facilities. The civilian facilities may be limited or prohibited in any area where it is determined that military facilities are adequate to care for the service families. Charges in military facilities are limited to subsistence and in hospital charges, together with uniform, minimal charges for outpatient care. In private facilities, the charges will be at the same rate or the first \$25 whichever is the larger. The law defines "military dependents," as well as the types of benefits provided in military and in civilian facilities. In supporting this program and pledging its complete cooperation, the A M A urged that increased emphasis be placed on the utilization of civilian facilities and the services of civilian physicians.

Public Law 763, 24 July 1956, is a permissive law authorizing the appointment of osteopaths as medical officers in all the military services. The American Medical Association opposed this measure, because it believed that the appointment of osteopaths as medical officers would endanger the health and welfare of military personnel, would contribute to the demoralization of the career services, would endanger the accreditation of residencies and internships in military hospitals, and would unnecessarily hinder the utilization of civilian consultants and other civilian physicians.

claimed was essential to get enough physicians to maintain high standards of medical care for military personnel. It also extended, for four years, the \$100 a month equalization pay for physicians and others on active military duty. Reflecting some of the objections of the American Medical Association in opposing an extension of the Doctor Draft Act, it amended the law by (a) lowering the age limit for call up of special registrants from 51 to 46 years of age and (b) exempting from induction special registrants over the age of 35 who had previously applied for commissions as medical or dental officers in one of the armed services if they had been rejected solely on the basis of a physical disability.

The Department of Defense has indicated to the Association that it will not seek an extension of the Doctor Draft. Legislation has been proposed to amend the basic Universal Military Training and Service Act to provide for the selective call up of physicians along with others who have general draft liability. Under the present basic draft act, physicians who have been deferred beyond age 26 to complete their medical education are liable for service up to age 35. The proposed legislation is designed to provide for an orderly call up of these deferred physicians.

Public Law 294, 9 August 1955, authorized reserve commissions for the first time for male nurses in the armed services. The A. M. A. took no position on this legislation.

Public Law 492, 27 April 1956, authorizes the President to make the U. S. Public Health Service a military branch in time of emergency involving the national defense. Prior to this, such status was permissible in time of war but not in time of emergency. The Public Health Service considered this change necessary to discharge adequately its new civil defense responsibilities. After the Surgeon General of the Public Health Service assured the Association that the proposed legislation would not be used for the purpose of placing calls for civilian physicians with the Selective Service System in time of national emergency, the American Medical Association then supported the measure.

Public Law 497, 30 April 1956, was designed to increase career attractiveness of military medicine. In addition to \$100 a month equalization pay, medical officers under the law receive an additional increase in pay of \$50 at the end of 3 years' service, another \$50 at the end of 6 years' service, and another \$50 at the completion of 10 years' service. The original version of the bill provided for the first pay increase at the end of 3 years. As finally enacted, it included the A. M. A. recommendation for an increase at the end of 3 years. Another A. M. A. recommendation not included in the law was for an increase at the end of 6 years.

The group studied nutritional problems and dietary deficiencies in France, Greece, Turkey, Lebanon, French Morocco, Iran, Pakistan, Eritrea, Ethiopia, and Libya. At Teheran, Iran, the committee met with the Surgeons General of Iraq, Turkey, Iran, and Pakistan to discuss nutritional problems in those countries.

While on the trip the committee also reviewed medical care provided for U. S. Military Assistance Advisory Group (MAAG) in the areas visited.

---

## DEATHS

**BARCLAY** Robert Maxwell, Lieutenant Colonel DC USAR of Glenshaw, Pa., stationed at 665th Medical Detachment, Korea, graduated in 1938 from Northwestern University Dental School, commissioned a First Lieutenant 8 October 1940 and ordered to active duty 1 July 1942; released from active duty in 1945 and returned to active service 13 October 1953; died 6 October 1956, age 44, in Korea of acute anterior myocardial infarction.

**YOUNG** Grayce Esther, First Lieutenant ResAF (AFNC) of Warden, Ohio, stationed at 4457th U. S. Air Force Hospital, Sewart Air Force Base, Tenn., graduated in 1949 from Saint Vincent & Charity Hospital School of Nursing, Cleveland, Ohio; ordered to active duty 5 August 1955; died 26 October 1956, age 28, in an aircraft accident.

---

**ERRATUM** The legend under the illustration on page 1830 of the December 1956 issue of this *Journal* should have shown Vice Admiral Roque A. Saldias as President of the Council of Secretaries instead of as Secretary of the Navy of Peru.—Editor

## COMMITTEE ON NUTRITION VISITS EUROPE AND MIDDLE EAST

Members of the Committee on Nutrition for National Defense recently completed a survey of countries in Europe and the Middle East. Dr. Frank B. Berry, Assistant Secretary of Defense (Health and Medical) and Chairman of the Committee, was accompanied on the 28-day tour by Rear Admiral Bartholomew W. Hogan, MC, USN, Surgeon General, U.S. Navy; Major General James O. Gillespie, MC, USA, Office of the Surgeon General, Department of the Army; Major General Harry Armstrong, USAF (MC), Surgeon, Air Force Europe; Dr. Arnold E. Schaefer, Deputy Director, Interdepartmental Committee on Nutrition for National Defense; Dr. Joseph S. Butts, Oregon State College, Corvallis, Ore., consultant to the Interdepartmental Committee; Dr. Olaf Mickelsen, National Institutes of Health, Bethesda, Md.; Dr. Richard A. Kern, Temple University Hospital, Philadelphia, Pa.; and Dr. Edward D. Church, Jr., John Homans Professor of Surgery, Harvard Medical School, Boston, Mass.

*Committee arriving in Washington, D. C., on their return from the Middle East. From left to right: Dr. Arnold E. Schaefer, Major General James O. Gillespie, MC, USA, Lieutenant Commander Thomas L. Hollis, MSC, USN, Rear Admiral Bartholomew W. Hogan, MC, USN, Dr. Joseph S. Butts, Lieutenant James W. Staudacher, USA, Dr. Frank B. Berry, Dr. Edward D. Church, Jr., Dr. Richard A. Kern, Dr. Olaf Mickelsen.*

Serman Prize for his article "Radiation Injuries Resulting from Nuclear Explosion and Fallout" which was published in the April 1956 issue of *Military Medicine*

The Stitt Award was presented to Lt Colonel Edwin J Pulaski MC USA, for his contributions in antibiotic research especially the use of antibiotics in burns

*Admiral Arthur W. Radford USN Chairman Joint Chiefs of Staff giving address at Association meeting*

The McLester Award for outstanding work in nutrition and dietetics was received by Captain Elinor Pearson AMSC for her metabolic studies of severely burned patients

Winners of the Founder's Medal were chosen by the Executive Council of the Association from members who have made outstanding contributions to military medicine and performed meritorious service to the Association. Those who received the medal for 1956 were

Major General George E. Armstrong USA (Ret.), former Surgeon General of the Army (1951-1955) now Director of New York University Bellevue Medical Center New York N. Y.

Captain Eugene V. Jobe MC USN Bureau of Medicine and Surgery Department of the Navy Washington D. C.

Captain Walton L. Jones MC USN Bureau of Medicine and Surgery Department of the Navy Washington D. C.

## BOOKS

### Reviews of Recent Books

**ADVANCES IN INTERNAL MEDICINE** Volume VIII edited by William Dock M D and I Snappe M D 366 pages illustrated The Year Book Publishers Inc Chicago Ill 1956 Price \$9

This eighth of a series deals with eight subjects in review form of which some are universal in interest and others more or less exotic in nature

**Disorders of Esophageal Motor Functions** by F J Ingelfinger is a lucid presentation of the anatomy and physiology of the esophagus Based on this data a realistic therapeutic approach has been formulated

**Peptic Ulcer Review of Recent Literature Pertaining to Etiology Pathogenesis and Certain Clinical Aspects** by J B Kirsner R S Kassriel and W L Palmer gives an excellent summary of the literature for the past five years The review of incidence the role of hydrochloric acid and the relations of serotonin and reserpine plus the problem of massive gastro intestinal hemorrhage are interestingly discussed Clinical indications for transfusions and surgical intervention are clearly given A reasonable conservative approach to the problem of gastric ulcer is offered

**Digitalis and Potassium** by B Lown is a key paper for anyone undertaking the treatment of cardiac patients Potassium metabolism is explained and factors enhancing myocardial sensitivity to digitalis following potassium deficit are enumerated Finally the interrelations of calcium potassium and digitalis are shown

J A Luetscher Jr discusses Aldosterone its pharmacologic actions extraction and measurement on body fluids and physiologic effects of its administration

**Adrenalectomy and Hypophysectomy in the Treatment of Advanced Cancer** by O H Pearson provides a brief resume of the subject In the case of carcinoma of the breast relationship of adrenalectomy to response to oophorectomy and androgen therapy is shown Preliminary results of hypophysectomy for breast cancer indicated about an over all 50 per cent improvement A program for hormone replacement therapy during and after adrenalectomy and hypophysectomy is given

**Chemotherapy of Tuberculosis** by W F Russell Jr S H Dressler and G Middlebrook is a review of antimicrobial action of drugs parasite susceptibility and drug resistance A most interesting facet presented is that of the prophylaxis of primary tuberculosis

H. A. Schroeder presents papers on "Trace Metals and Chronic Diseases." Five trace metals believed essential for mammalian metabolism—manganese, copper, cobalt, zinc, and molybdenum—are discussed. The possible relation of trace metals to chronic diseases such as hypertension, atherosclerosis, disseminated lupus, and others is suggested.

R. Janet Watson presents "Hemoglobins and Disease" and discusses 11 hemoglobins other than the normal. Seven combinations with normal hemoglobin resulting in a symptomless trait and 14 combinations with other abnormal genes resulting in pathologic conditions are presented.

The best portion of this book, at least for the inquisitive reader, is the extensive bibliography to be found at the end of each review.

—ARCHIE A. HOFFMAN, Col. USAF (MC)

**ROENTGEN INTERPRETATION** by George W. Holmes, M.D., and Laurence L. Robbins, M.D. 8th edition. 525 pages. 371 illustrations. Lea & Febiger, Philadelphia, Pa. 1955. Price \$10.

For those in the early stages of training in radiology, this modest-sized text can perform an important service. The authors do not attempt to be encyclopedic or exhaustive, and by so doing they are able to present basic ideas in relatively brief form. All too often, sometimes, the student bogs down in a massive text or in the periodical literature and is unable to see the forest for the trees. At such times the eighth edition of this well-known work can furnish a quick and lucid re-orientation.

In condensing the material, the authors have avoided the temptation to outline and list classifications. Instead, they adhere to a straight expository style with a smooth flow of ideas from one topic to the next. The illustrations are aptly chosen and the technique of reproduction is of the highest quality.

The first chapter on "Confusing Shadows and Artefacts" has much to recommend it to the beginner. Following this introductory effort, the writers successively discuss radiology of bones, joints, chest, and gastro-intestinal and genito-urinary tracts. The final chapter covers fluoroscopic technique and radiation protection.

Within the limits which the book sets for itself with respect to space and expense, it is fair to say that the stated objective—"to present the essentials"—is admirably accomplished.

—JAMES T. BRENNAN, Lt. Col. MC USA

**Williams OBSTETRICS** by Nicholson J. Eastman. 11th edition. 1,212 pages, illustrated. Appleton-Century-Crofts, Inc., New York, N.Y. 1956.

The 11th edition of this book is the most up-to-date obstetrical text book available. The editor has made many major revisions and deleted much outdated material. Dr. Louis M. Hellman revised several sections, including anesthesia and analgesia, uterine inertia, and rupture of cesarean section scars. An excellent chapter on the psychiatric aspects of pregnancy and childbirth is presented. The book has

attractive to the reader by addition of many excellent new illustrations several of which are in color. The new material presented on Rh in compatibility is excellent. There are new or improved sections on fibrinogenopenia postmaturity hypotensive drugs retrolental fibroplasia adrenocortical hormones and management of habitual abortion. The section on iron metabolism and anemia in pregnancy and the treatise on the toxemias of pregnancy are attractive presentations. The bibliography has been brought up to date and is quite extensive.

As an obstetric text it is unsurpassed it not only appeals to the student intern and resident but is especially satisfactory to the teacher general physician and the specialist — *J WILSON HUSTON Capt MC USN*

**TECHNIQUES AND PROCEDURES OF ANESTHESIA** by *John Adriani M D*  
2d edition 508 pages illustrated Charles C Thomas Publisher Springfield Ill 1956 Price \$8.75

Dr Adriani has revised the original 1947 edition by several additions and has deleted techniques which have not proved useful. The text consists of nine parts totaling 535 pages which cover the field of anesthesiology. Included in these nine chapters are selections on anesthesia specialized procedures and resuscitation and inhalation therapy. Each part is devoted to the methods and uses of those agents under discussion. Complications of anesthesia are discussed in a separate chapter while the short appendix offers tables of ordinary laboratory values and cardiac hemodynamics.

The text is unusual as it presents information in outline form with check lists for almost any situation. These check lists cover in precise fashion indications and contraindications advantages and disadvantages premedication methods and techniques. Selection of anesthesia is covered in a table indicating problems encountered or anticipated choice of agent and choice of technical procedure.

The book is well illustrated and adequately referenced and the author suggests its use by beginners. I believe this work also merits the attention of the expert who desires a time saving reference and would recommend it for the library of all practicing anesthesiologists.

—*ROBERT F. CORWIN Col USAF (MC)*

**PHYSICAL DIAGNOSIS** by *Ralph H Mayo M D* and *Mahlon H Delp M D*  
5th edition 358 pages illustrated W B Saunders Co Philadelphia Pa 1956 Price \$7

This is a revised edition of a widely used textbook in physical diagnosis. It includes for the first time Dr Mahlon H Delp as the co author.

There are sixteen chapters and an interesting introduction includes a brief history of physical diagnosis and its major contributors. The book is so subdivided and classified that it may be studied as a text in the order written or in any desired fashion. It is recommended reading for all practitioners of medicine but not intended as a reference book or encyclopedia. Possibly for this reason details and discussion of the

fundamentals and methods of palpation percussion and auscultation at times have been excessively abbreviated. This is a highly recommended text which will undoubtedly receive the same wide approval the previous editions have enjoyed — *KUFUS J. PLARSON Jr Col MC USA*

**PROCEEDINGS OF THE INTERNATIONAL CONFERENCE ON THE PEACEFUL USES OF ATOMIC ENERGY** Held in Geneva 8 August 20 August 1955. Volume 10. Radioactive Isotopes and Nuclear Radissions in Medicine. 544 pages illustrated. United Nations Publications, 1956. Distributed by Columbia University Press New York, N. Y. 1956. Price \$8.

This publication volume 10 of a 16-volume series records the proceedings of the International Conference on the Peaceful Uses of Atomic Energy held at Geneva Switzerland from 8 to 20 August 1955 under the auspices of the United Nations. Eighty-five original papers with minor editing are included as well as appropriate verbatim records of the conference. The papers by leading authorities of the various countries cover a wide range of subjects indicating experiences with accepted uses of isotopes as well as suggestions for future studies. The majority of papers are oriented toward direct human applications of diagnosis and treatment in the fields of endocrinology, metabolism, hematology, and cancer. Excellent papers are also presented in the general fields of biochemistry, nutrition, and public health including studies in mosquitoes and helminths. Other than for the few frankly review papers all material is heretofore unpublished data representing variations in methodology or adaptations of previously published principles.

One is impressed with the world wide impact of these relatively new techniques in the practice of medicine. With an increasing number of reactors available for isotope production throughout the world clinical specialists and biologists will have opportunities to use these materials as an aid to understanding their particular problems as well as those of general interest.

This entire series of books should be a valuable addition to medical libraries for both its historical and technical interest.

—*JAMES B. HARTGERING Lt Col MC USA*

**CHANGING CONCEPTS OF PSYCHOANALYTIC MEDICINE** Proceedings of the Decennial Celebration of the Columbia University Psychoanalytic Clinic March 19 and 20 1955 edited by Sandor Rado M.D. D. Pol. Sc. and George E. Daniels M.D. 248 pages Grune & Stratton Inc. New York N. Y. 1956. Price \$6.75.

The articles contained in this volume are based on papers presented at the Decennial Celebration of the Columbia University Psychoanalytic Clinic held in March 1955. The contributors are an erudite group most of whom are faculty members of the Clinic. The volume sets forth the outstanding accomplishments of this Clinic by infusing an atmosphere of free inquiry into psychoanalysis and by incorporating psychoanalytic techniques into graduate medical training in a unique atmosphere of training the selection of students.

curriculum are described. The contents of the book demonstrate the great indebtedness of the faculty to the energy and guidance of Dr Sandor Rado whose "adaptational psychodynamics" has been built upon the theories of Freud and realigned them in terms which are biologically oriented. A diagnostic survey is presented of the clinic's case load with the finding that 59.3 per cent of the applicants for treatment were diagnosed as having schizophrenia. The discussion of diagnostic criteria and the implications of this figure are of great interest.

Psychotherapy is usefully termed as reparative or reconstructive in nature and the application of these differing therapeutic approaches to clinical cases is described. On a clinical level the changing concepts of psychoanalysis are dramatically outlined in papers on a Family Study Unit and on interlocking pathology in family relationships. Such a broad inclusive approach is also evident in a paper by Kardiner examining adaptational theory from a cross cultural point of view and in Glueck's study of psychodynamic patterns in the sexual offender. Perhaps of greatest interest to the reader in showing the wide reorientation of this psychoanalytic group are the papers by Daniels on comprehensive medicine and by Gerard and Heath on brain physiology and multidisciplinary research in psychiatry.

This is an excellent volume well written and an excellent commentary on the best of present day thinking in psychiatric training, treatment and research. It will be of interest to all working in psychiatry especially if engaged in teaching and research. —JOHN C. MEBANE Maj USAF (MC)

**PSYCHOANALYSIS OF BEHAVIOR** Collected Papers by Sandor Rado M.D.  
D. P. Sc. 387 pages Grune & Stratton Inc. New York N. Y. 1956  
Price \$7.75

In this work Dr. Rado has assembled his personal writings during the period from 1922 to the present. The earliest papers were published in Vienna and London during the time when the author was director of the Berlin Psychoanalytic Clinic. These papers were written under the spell of Freud's influence and are essentially contributions to classical psychodynamics. Perhaps the most valuable of these is "The Psychoanalysis of Pharmacohymia (Drug Addiction)" published in 1933 but a model for those who deal with this problem today.

Dr. Rado has entitled the second portion of his collected papers "Quest for a Basic Conceptual Scheme." The papers in this section were developed after the author had emigrated to the United States and had begun to exert what has become an appreciable influence on the course of psychoanalysis and psychiatry in this country. He had by this time become dissatisfied with Freud's formulations and sought to re-construct them in a biologic frame of reference. Rado's paper "Scientific Aspects of Training in Psychoanalysis" (1938) signals his effort to present psychoanalysis as "an empirical clinical science not an authoritarian theoretical doctrine." Included in this section is "Pathodynamics and Treatment of Traumatic War Neurosis" (1942) in which the author sets forth a timely and accurate perspective to guide psychiatry during the challenging period of World War II.

In 1946, the author's explorations bore fruit in the development of "Adaptational Psychodynamics." Further contributions to graduate residency training in psychoanalytic medicine were made. "An Adaptational View of Sexual Behavior" and "Emergency Behavior," two of Dr. Rado's greatest contributions are elucidated in graphic style well supported by diagrammatic illustrations. In a discussion of "Recent Advances in Psychoanalytic Therapy" the author describes the adaptational technique and compares it with the chief therapeutic ideas evolved in the past. Future problems include the pressing social need for trouble shooting and easing methods of treatment. The physician's emotional needs and their impact upon treatment should also be explored. The author regards this as a neglected chapter of inquiry.

The "Dynamics and Classification of Disordered Behavior" (1953) presents the author's own psychiatric nomenclature. This unfortunately adds little but confusion to the newest standard nomenclature of the American Psychiatric Association which was introduced at about the same time. Although the terminology differs the underlying thinking appears very similar.

In summary, this is an excellent work for the student who wishes to study present-day trends of psychoanalytic thought. The writing style is lucid and the ideas expressed would be stimulating to anyone interested in human behavior. The book will be of especial value to psychiatrists and a "must" for those engaged in psychoanalytic therapy.

—JOHN C. MEEHAN, Maj, USAF (MC)

NEUROLOGICAL AND NEUROSURGICAL NURSING by C. G. de Gutierrez Mahoney, M.D. and Esta Carini, R.N., M.A. 2d edition. 565 pages illustrated. The C. V. Mosby Co., St. Louis, Mo., 1956. Price \$6.25.

The current edition of the "only textbook of its kind" deserves nothing but high praise for the authors who have most admirably achieved their purpose—that of meeting the need for effective nursing care in these specialties. A comprehensive covering of such a highly specialized field has long been needed for the nursing profession and with the inclusion of several new chapters in this edition the goal has been most effectively attained.

To provide an understanding of the signs and symptoms of neurologic disorders, an excellent presentation of neuroanatomy, physiology and the related scientific principles is given in the early part of the text. Diagnostic procedures are completely discussed and the importance of nurses' observations are emphasized throughout. The authors have successfully integrated physical, social and emotional factors of illness in planning nursing care as shown by their statement: "An understanding of the underlying mechanisms motivating human behavior is an essential requisite of the well qualified nurse."

This book is strongly recommended for both nurses. It is an excellent reference text for

head nurses and especially for those who give direct nursing care to all types of patients. This book is so written as to provide the professional nurse with a wealth of information related to total patient care.

—VERA E. THOMPSON, Lt. Comdr. NC, USN

**A Manual of the COMMON CONTAGIOUS DISEASES** by Philip Moen Stinson, M. D. and Horace Louis Hodges, M. D. 5th edition. 624 pages. 84 illustrations and 10 plates. 8 in color. 16 tables. Lea & Febiger Philadelphia, Pa. 1956. Price \$5.50.

This is an extensive volume which covers the field of common contagious diseases in a very thorough manner. The format of the book is excellent and the complete detail makes this a superb text which should be available to all teaching personnel or physicians treating the diseases.

The first three chapters are devoted to principles of contagion, serum reactions and the antibiotics and sulfonamides. These chapters provide an excellent refresher and ready reference for those who require it. There is a very complete summary of the common contagious diseases in table form covering all of the pertinent points for quick reference.

The black and white photomicrographs are clear, the black and white illustrations are quite good. The color plates are superior and the authors and the publisher are to be complimented on them.

The final chapter gives a good resume of the general management of contagious diseases which should be made available in hospitals that provide care in these diseases.

It appears that the authors intended this book to be used as a reference in teaching and in the care of common contagious diseases. Their efforts have produced a book which should be in the hands of all physicians engaged in public health, preventive medicine, pediatrics and teaching activities. —THEODORE C. BEDWELL, J. Col. USAF (MC)

**HANDBOOK OF PEDIATRIC MEDICAL EMERGENCIES** by Adolph G. De Sanctis, M. D. with the collaboration of Charles Laiga, M. D. and 10 contributors. 2d edition. 389 pages. 73 illustrations. The C. V. Mosby Co. St. Louis Mo. 1956. Price \$6.75.

The second edition of this handbook has been largely rewritten and has been expanded to include new chapters on metabolic emergencies, accident and poison prevention, genito-urinary emergencies and respiratory paralysis in poliomyelitis.

This is a compact, well written and immensely practical handbook for all physicians treating children. The sole purpose of this book is to outline sound therapeutic advice to guide the physician in handling emergency pediatric problems. It is not meant to be a complete text of pediatrics but a reliable guide for the physician facing a pediatric problem requiring rapid emergency therapy.

The authors have succeeded admirably in their purpose. For the earlier edition of this book has been enthusiastically received not only in

the United States but also in many foreign countries. The chapters are short and succinct and suggest readily available therapeutic agents of life saving importance in treating the emergencies described. The authors cover not only the common serious emergencies but also many less serious though still troublesome, emergencies such as insect bites, toothache, epistaxis, hiccough, frostbite and sunburn.

The text is well organized and is supplemented with a comprehensive and well organized index—a must for a book such as this. This book is highly recommended for any physician caring for children.

—THOMAS E. CONE, Jr. Col. MC USA

PROGRESS IN PSYCHOTHERAPY 1956, edited by *Frieda Fromm-Reichmann* M.D. and *J. L. Moreno* M.D. 352 pages Grune & Stratton Inc. New York N.Y. 1956. Price \$8.50

This volume is the publication in book form of the papers presented at the meeting of the American Psychiatric Association in Atlantic City 1955. To these there have been added brief surveys of the field of psychotherapy in Austria, Great Britain, France, Germany, South America and Switzerland.

One hundred and forty-two different techniques are mentioned in all from the psychodrama of Moreno and existential analysis to autogenic training and multiple therapy of Whitaker. More than forty psychotherapists from many parts of the world contributed to the volume. While the descriptions of some of the techniques are necessarily brief, yet the editors do succeed in giving the reader an easy opportunity to compare different philosophies and methods.

The book points out quite clearly that psychotherapy is not a science and that no technic can claim superior results. It suggests that the personality of the therapist may be the most important fact. Moreno states bluntly that "The personality of the therapist is the skill." The book is heartily recommended for residents in psychiatry in particular and to all those who wish to have a quick glance at the various types of psychotherapy.—JAY F. TUTTLE, Lt. Col. MC USA

THE YEAR BOOK OF PATHOLOGY AND CLINICAL PATHOLOGY (1955-1956 Year Book Series) edited by *William B. Wartman* M.D. 480 pages illustrated. The Year Book Publishers, Inc. Chicago Ill. 1956. Price \$6.50

This yearbook, similar to its predecessors, summarizes concisely the important literature of pathology for the year 1955. The format of the volume is essentially the same as in previous years; that is, the book is divided into two main sections: pathology and clinical pathology, with further subdivisions into the main categories of these disciplines. The introduction, stating how the volume is compiled, demonstrates the huge amount of literature covered.

The editor has again done a fine job in condensing a large amount of material and presenting it in a lucid, readable form with other references. Editorial comments throughout.

ticularly valuable indicating the significance of the article and relationships to both past and present work. The illustrations and graphs frequently add to the usefulness of the text. While there are occasional typographical errors they do not detract from the value of the book as the context is always clear. The book is invaluable as a ready reference and review of the literature. It is highly recommended to pathologists as well as to physicians in general. —HOWARD A. VAN AUKEN Col. MC USA

**THE ACCIDENT SYNDROME** The Genesis of Accidental Injury A Clinical Approach by Morris S. Schulz M. A. M. D. 234 pages illustrated Charles C Thomas Publisher Springfield Ill. 1956. Price \$6.50

This book is based on data collected from 35,000 consecutive accident cases seen by the author over a period of 20 years. Because of his interest in the circumstances surrounding each accident and in the patient's emotions and past history, his data is unusually illuminating.

Throughout the book the importance of more medical interest in accident prevention is stressed and the arguments are very convincing. The major findings and conclusions are contained in the second chapter. This departure from more orthodox organization is not objectionable and serves to develop more reader interest. The third chapter deals with concepts of accident causation and proves to be an excellent presentation of previous work on the emotional aspects of accident causation.

The author's data confirms many previously formulated ideas on accident-causation presenting the concept of the accident syndrome. He indicates the possibility of predicting with reasonable certainty when, to whom and under what circumstances an accident is most likely to occur. The widely accepted theory which attributes most accidents to a small, fixed group of accident-prone individuals is challenged by the author's data which indicates that this small group of accident-prone individuals is constantly changing.

This book should be of value to physicians in general but particularly to those treating accident cases and to the psychiatrist.

—JAMES J. GIBBS Maj. MC USA

**INFANT METABOLISM** Proceedings of the World Health Organization Seminars Held at Leyden and Stockholm in October-November 1950 conducted by E. S. Gorter, S. Z. Levine and A. D. Wallgren. Edited by Herbert Scheberg. 435 pages illustrated. The Macmillan Co. New York N. Y. 1956.

The purpose of these seminars was to bring together a group of leading medical investigators with special interest in the broad fields of infant metabolism so that scientific information might be exchanged on a research level among countries where such studies were currently in progress. Nine countries and 21 universities were represented. In broad terms, the theme of the two seminars was similar and embraced current physiological, biochemical, nutritional and clinical problems in infant metabolism. The topics reviewed in individual panels are presented as separate chapters in the volume.

The panel on water and electrolyte metabolism dealt mainly with the role of sodium and potassium. The role of the steroids and other hormones in water balance was only briefly discussed while the panel on metabolism in premature infants was very interesting. The studies on fat metabolism lead to contradictory results as authorities from various countries could not substantiate each other.

The discussions of metal, vitamin and protein metabolism are mainly concerned with experimental information and have little value to the practicing pediatrician. Variable basal metabolic rates were obtained in children under four years of age and it was concluded that there is still little that is known of basal metabolism in infants.

This publication is not for the general practicing pediatrician but is a valuable reference book for one interested in research in metabolism. It has little or no bibliography and is of little value as a source book.

— WILLIAM I. NEMURA, *Corvallis, OR, USA*

**COLLECTED PAPERS OF THE MAYO CLINIC AND THE MAYO FOUNDATION**, edited by *Richard M. Heintz M. A. M. D.*, *John R. Miner Sc. D.*, *James R. Eckman M. A. Ph. D.*, *Katharine Smith B. A.*, *Carl W. Gambill M. D. M. P. II.*, *Florence Schmidt B. S. E.*, and *George G. Stillell M. D.* Volume XLVII 1955. 791 pages illustrated. W. B. Saunders Co. Philadelphia Pa. 1956.

This volume is a compilation of the publications from the Mayo Clinic and the Mayo Foundation from 1 December 1954 through 30 November 1955. It is comprised of 137 articles presented in full, in abridged form or in abstract that were selected from a total of 734 papers. Bibliographies of the unpublished papers appear at the end of appropriate sections. The editorial staff has selected for inclusion an outstanding group of papers. Some deal with the present activities in the Mayo Clinic describing recent efforts and advances. This is particularly true of the first section devoted to "Surgery of the Heart and Blood Vessels with Special Reference to the Extracorporeal Bypass Pump Oxygenator." Other papers reflect the vast experience of the Clinic in selected disease states. The photographs, charts, drawings, and graphs liberally used by some of the authors are excellent in their conception and clear in reproduction.

The papers represented and those listed by title only are divided into 13 main groups. Those recorded by title only are presented alphabetically by author, together with the subject and the medium wherein it is published. A complete listing is repeated at the end of the book. The subject index at the end of the book covers the contents of the published papers but unfortunately does not cover the papers listed by title only.

This annual presentation of the accomplishments of the Mayo Clinic and Foundation is of great value to all physicians in their special interests. It is a must for medical libraries.

—PA

**CYTOLOGY OF THE BLOOD AND BLOOD-FORMING ORGANS** by Marcel Bessis M. D. Translated by Eric Ponder M. D. 629 pages 427 illustrations including 22 full-color plates Grune & Stratton Inc. New York N. Y. 1956. Price \$22

Workers in the field of hematology will appreciate Marcel Bessis' book which deals principally with the study of blood cells in their living state and of their ultrastructure utilizing the latest methods and techniques including electron and phase microscopy. It brings together much reliable information about recent advances in hematologic techniques. The contents cover 15 chapters divided into three parts.

This book is up-to-date and the coverage of the literature is adequate as each chapter has an excellent bibliography which is truly international in character. It is printed on good paper with large readable type. The text is profusely illustrated with color plates and many remarkable photomicrographs of living cells made with phase microscopic techniques as well as those of fixed blood cells made with electron microscopic techniques.

This reviewer was very favorably impressed by the readability of the book and with its clarity and elegance—an accomplishment in a large measure attributable to the excellent translation by Dr. Ponder. Here available in English is a volume that should be widely read especially by those seeking information and orientation in the rapidly developing field of hematology. It can be recommended for reading or reference to the clinical pathologist and the internist as well.

—CHARLES J. FARINACCI Col. MC USA

**A NEW PSYCHOTHERAPY IN SCHIZOPHRENIA** Relief of Frustration by Symbolic Realization by Marguerite Sechebaye translated by Gaele Rubin-Rabson, Ph. D. 199 pages Grune & Stratton Inc. New York N. Y. 1956 Price \$4.50

The treatment of schizophrenia by psychological means is always an interesting subject and in recent years a number of books have been written using various approaches each attempting to point the way.

This book is a translation of a series of lectures given to the medical staff of the Burgholzli Psychiatric Clinic in Switzerland by Mme Sechebaye. Her method is called symbolic realization and is described as a therapy aimed directly at the needs and frustrations endured in childhood to fulfill and satisfy them on the presymbolic magic and concrete level. In formulating the method of therapy she draws heavily upon psychoanalytic and existentialist concepts as well as on genetic psychology. However the necessity of using ordinary psychiatric techniques such as an adequate history and questioning of relatives is emphasized. The constitutional factor is not underestimated and in certain cases strictly organic therapy may be employed to facilitate contact with the patient.

Schizophrenic symptoms are carefully analyzed and are divided into four categories: first those manifestations directly expressing the

January 1957)

## RESULTS OF TREATMENT

187

psychotic experiences second the experience of frustration such as aggression guilt and anxiety the third the experience of positive reactions to frustration in some cases as seen typically in paranoia and fourth the experience of the needs themselves in symbolic form.

Divining and as testing the needs in the appropriate fashion is the task of the therapist. This may even take the form of assisting patient to play the part of an infant — to take satisfaction from other satisfactions of early life etc. in fact or symbolically depending on the level of its current state. See above discussion of various problems involved and also heavily on the case of Florence a schizophrenic whom the method successfully treated. She does not claim her method is a panacea for schizophrenia and even so the difficulties involved. The book is provocative and stimulating but not easy reading. It should be of interest to any psychiatrist treating psychotic patients — JACQUES TIGHE, M.D.

ORAL CANCER AND TUMORS OF THE JAW by George A. H. Weldon & Bullock M.D. M.C. (Hartford) & John E. Lippert M.D. 360 pages illustrated. The Blakiston Division, Philadelphia, Pa. Inc. New York, N.Y. 1956. Price \$15.

This is the first edition of a book concerned with the clinical diagnosis of oral cancer and collaborated on by a surgeon a pathologist and a specialist in oral cancer diagnosis. In the author's preface this is not a textbook but a syllabus for the oral diagnosis course.

The basic organization of the material is good and the inclusion of chapters on the history of cancer the origin of cancer classifications of oral neoplasms, a discussion of biopsy procedure and a brief discussion of precancerous lesions will be an aid and a review to the clinician.

The text is generally well written, however a few statements are made and terms used which are debatable or open to question. The small paragraph devoted to the so-called retinal anlage tumor leaves the reader with the impression that the retinal origin is relatively well established. This tumor is considered by some pathologists as odontogenic in origin. The inclusion of the term "odontogenic" is unfortunate since the use of "odontogenic" is acceptable and well established in the literature. The discussion of the pathogenesis of ameloblastoma with emphasis upon the basal-cell theory of origin might be questioned by many oral pathologists, especially in the United States.

The great value of the volume lies in the multitude of excellent illustrations. Especially worthy of note is the high degree of technical proficiency used in the preparation of the roentgenograms for routine. This book will be of value to all practicing dentists especially periodontists and oral surgeons. Physicians who are concerned in their practice with the diagnosis and treatment of oral lesions, especially neoplasms will also find this book useful. — WILLIAM SPRAGUE, CHS, USA (DC)

**CYTOLOGY OF THE BLOOD AND BLOOD-FORMING ORGANS** by *Marcel Bessis* M D Translated by *Eric Ponder* M D 629 pages 427 illustrations including 22 full-color plates Grune & Stratton Inc New York N Y 1956 Price \$22

Workers in the field of hematology will appreciate Marcel Bessis' book which deals principally with the study of blood cells in their living state and of their ultrastructure utilizing the latest methods and techniques including electron and phase microscopy. It brings together much reliable information about recent advances in hematologic techniques. The contents cover 15 chapters divided into three parts.

This book is up-to-date and the coverage of the literature is adequate as each chapter has an excellent bibliography which is truly international in character. It is printed on good paper with large readable type. The text is profusely illustrated with color plates and many remarkable photomicrographs of living cells made with phase microscopic techniques as well as those of fixed blood cells made with electron microscopic techniques.

This reviewer was very favorably impressed by the readability of the book and with its clarity and elegance—an accomplishment in a large measure attributable to the excellent translation by Dr. Ponder. Here available in English is a volume that should be widely read especially by those seeking information and orientation in the rapidly developing field of hematology. It can be recommended for reading or reference to the clinical pathologist and the internist as well.

—CHARLES J. FARINACCI Col. MC USA

**A NEW PSYCHOTHERAPY IN SCHIZOPHRENIA** *Relief of Frustrations by Symbolic Realization* by *Maguerite Sechebaye* translated by *Gace Rubin Rabson* Ph D 199 pages Grune & Stratton Inc New York N Y 1956 Price \$4.50

The treatment of schizophrenia by psychological means is always an interesting subject and in recent years a number of books have been written using various approaches each attempting to point the way.

This book is a translation of a series of lectures given to the medical staff of the Burgholzli Psychiatric Clinic in Switzerland by Mme. Sechebaye. Her method is called "symbolic realization" and is described as a therapy aimed directly at the needs and frustrations endured in childhood to fulfill and satisfy them on the presymbolic and concrete level. In formulating the method of therapy draws heavily upon psychoanalytic and existentialist concepts as well as on genetic psychology. However the necessity of using psychiatric techniques such as an adequate history and physical relatives is emphasized. The constitutional factor is not and in certain cases strictly organic therapy may be facilitated contact with the patient.

Schizophrenic symptoms are carefully analyzed and four categories first those manifestations directly

Undoubtedly, the people engaged in the search for truth by Dr. Burch exist and, by the same token, the people engaged in the search for truth by other individuals who do not agree with Dr. Burch. The unknown will derive keen and quiet enjoyment from a perusal of this book which is clearly illustrated in a very interesting and severely critical manner.

DIAGNOSIS AND TREATMENT OF VASCULAR DISEASES, 1922, edited by Saul S. Sarnoff, A. M., M. D., with 100 illustrations, illustrated. The Williams & Williams Co., Baltimore, Md. 1922. \$6.

The editor of this volume has called upon the extensive knowledge and experience of 17 contributors who have a masterful grasp of the subjects. Each is a nationally known authority in his specialty, these range from anatomy, physiology, internal medicine, and surgery to physical medicine.

With the exception of the chapter on the anatomy of the peripheral circulation which necessarily is brief, all of the subjects are covered in a very comprehensive manner. Of especial interest to the diagnostician is the section on examination of the patient which includes not only the various ramifications of the history and physical examination, but the invaluable laboratory methods of interpretation. Prominent among these is the discussion on plethysmography. In addition to the conditions treated primarily by medical methods, the present emphasis in the surgical management of aneurysms is clear, acute arterial thrombosis and aortic lesions are adequately presented. In addition the chapter on anticoagulant therapy is also included.

Each chapter has an extensive bibliography for the reader who wishes to further investigate vascular disorders, and the text abounds with excellent illustrative charts and photographs. A prime example of this is the chapter on angiography.

It is believed that this book could profitably be read by all internists and surgeons who may be confronted with vascular problems. It would also make an authoritative addition to the library of those particularly interested in the entire subject of angiology which includes both medical and surgical components of vascular disorders.

TEXTBOOK OF UPOLOGY By Victor F. Marshall M.D. (4 pages illustrated)  
Paul B. Hoeber, Inc., Medical Book Dept. of Harper & Bros., New York,  
N.Y. 1956 Price \$5.50

This book was developed from 20 formal lectures given to third year medical students by various lecturers and revised by the author. It is relatively small in size when compared with most of such texts. A short history of urology is given in a clear and concise manner which includes an excellent summary of the various methods, including laboratory tests, to be employed in the performance of urologic investigation. Each of the chapters contains simple, succinct, yet complete sections on the

**CLINICAL SELECTIONS IN DERMATOLOGY AND MYCOLOGY** by *Federick Rehm Schmidt* M D with contributions by 36 specialists from various lands 505 pages Charles C Thomas Publisher Springfield Ill 1956 Price \$10 50

As its title implies this book is made up of selected readings on many varied subjects in the fields of dermatology and mycology Dr Schmidt the author of 14 chapters has edited the other 29 chapters contributed by 36 specialists mostly physicians and scientists of the various American countries Many of the chapters are excellent having been written by authorities on the particular disease or subject under discussion Their writings reflect excellent first hand observations and concise reporting A few chapters however are too superficial and brief in the handling of the subject matter and therefore of limited value

The relationship of climate personal hygiene environment and diet in the diseases considered is frequently discussed Much can be learned from this book about dermatologic conditions or diseases with dermatologic manifestations which are uncommon in the United States Treatment of the diseases where applicable is discussed in a logical and concise manner using whenever possible drugs which are universally available A number of controversial opinions and original ideas are expressed and these will prove stimulating and thought provoking for the seasoned dermatologic reader

This book is well written and well edited and covers many subjects in an interesting and informative manner It should be read by all dermatologists and by other physicians interested in one or more of the discussed diseases and belongs in all medical reference libraries

—JOHN W ALBRITAIN Capt MC USN

**OF RESEARCH PEOPLE** by *George E Burch* M D F A C P 56 pages illustrated Grun & Stratton Inc New York N Y 1955 Price \$3

This is a short book of 56 pages The cryptic duties of the galaxy of "research people" from the responsible investigator to the dish washers are presented in terse description and pointed caricature

Dr Burch describes the true investigator as one with the ability make discoveries and differentiates between the scientists who discover and the individuals who provide a new or different application or development His contention that discoveries are made by man development by many will be accepted by the searchers However his opinion that the best research is in the laboratory by an able investigator either alone or in the presence of not more than one or two competent technicians quality of research tends to vary inversely with the number of assistants will be seriously questioned by many investigators instances where team work by several individuals in different scientific disciplines were able to obtain the solution that would have remained unsolved by the effort of a single investigator

**SELECTED PAPERS ON PSYCHO-ANALYSIS** Volume I On the Early Development of Mind, by *Edward Glover* M. D. 493 pages International Universities Press Inc., New York, N. Y. 1956 Price \$7.50

In his inimitable literary style, which has both clarity and picturesque imagery Dr. Glover presents in this collection of selected papers on psychoanalysis a very worthwhile study of the early development of the mental and emotional processes of the human individual. While the book requires a basic understanding of psychoanalytic principles and concepts it serves to unite many of these concepts and principles into a more usable form. Particularly impressive are the scientific standards which Dr. Glover requires of himself and others in presenting various aspects of the science of psychoanalysis. Of particular interest are his papers on the psychology of the psychotherapist, the application of psychoanalytic principles in psychiatry, research methods in psychoanalysis and the indications for and frontiers of, psychoanalysis. All of these papers emphasize the advances important in the future of psychoanalysis in scientific medicine.

While this volume is of most value to serious workers in psychoanalysis whether student or analyst it will provide many other professional students of human behavior with both scientific information and a literary masterpiece.

This is an excellent companion to Dr. Glover's book *The Techniques of Psychoanalysis*. Both books should be in the working library of professional workers in psychoanalysis. —*LEON GATTO* Col. USAF (MC)

**THE NEUROSURGICAL ALLEVIATION OF PARKINSONISM** by *Irving S. Cooper* M. D. Ph. D. 104 pages illustrated Charles C. Thomas Publisher Springfield Ill. 1956 Price \$8.50

This monograph clearly and concisely presents the author's technique for the alleviation of the most severe symptoms of parkinsonism by occlusion of the anterior choroidal artery and chemopallidectomy. He first reviews the problem of severe parkinsonism and the efficacy of the medical and previous surgical approaches to remedy the main symptoms of this disease. The anatomy, functions and blood supply of the globus pallidus and its role in the parkinsonian complex are described. There is a complete review of the author's operations for occlusion of the anterior choroidal artery and chemopallidectomy including the selection of suitable cases for each procedure, anesthesia, the importance of pre- and post-operative arteriograms, postoperative care and the operative mortality.

Case reports of 15 patients with anterior choroidal artery occlusions and 10 patients with chemopallidectomy are presented and include many pre- and post-operative photographs. The text is also well treated with excellent sketches of the operative technique.

This text is primarily intended for neurologists but will also find the case histories

The author should be commended for this excellent presentation of his operative material and it is hoped that his record of 70 per cent improvement in these cases will be of a lasting nature.

—WILLIAM J. JAMES Capt MC USA

**BIOCHEMICAL MECHANISMS IN INFLAMMATION** by Vally Menten M. A. M. D. 2d edition completely revised Edited by Edward J. Ryan, D. D. S. 438 pages illustrated Charles C. Thomas Publisher Springfield Ill. 1956. Price \$9.50

The second edition of this monograph on biochemical mechanisms in inflammation has been expanded and now includes observations by many investigators as well as the author. The material is presented in an integrated manner and the reader is introduced to recent facts and theories of inflammation. The author has long maintained that in inflammation the altered biochemistry of the injured cell causes the liberation of biochemical units. This theory is reviewed and examined in the light of additional data obtained by the author. New material has been added regarding the pyrogenic factor, the anti-inflammatory corticoids and ACTH.

This book is of interest to those who wish to probe into the biochemical mechanisms of the injured cell in inflammation.

—ELSON B. HELWIG Col MC USA

**COMPLETE MOUTH REHABILITATION THROUGH CROWN AND BRIDGE PROSTHODONTICS** by Harry Lazar D. M. D. and Albert J. Lazar D. M. D. 392 pages 551 illustrations on 332 engravings Lea & Febiger Philadelphia Pa. 1956. Price \$15

The text of this book which is prepared in three parts is a guide to full mouth rehabilitation through crown and bridge prosthodontics. The first part sets forth fundamental principles, theories and functional aspects of rehabilitation. Chapters on anatomy of the temporomandibular joint, physiology of mastication, physiologic rest position, vertical dimension, occlusion and periodontal considerations are capably presented. The second reports 25 cases involving typical mutilated dentition problems encountered in practice. The methods and techniques employed by the authors for diagnosis, planning and treatment are discussed in each case. The third part opens with a discussion of anesthesiology in relation to crown and bridge prosthodontics while following chapters present operative and technical factors in considerable detail. The text is concluded with a pictorial description of a technique for construction of movable removable precision attachment partial dentures.

Excellent organization of the text and a concise manner of presentation lend themselves to easy reference and reading while well selected illustrations augment and clarify the text.

—ARTHUR R. FRECHETTE Capt DC USA

**BASIC READINGS ON THE MMPI IN PSYCHOLOGY AND MEDICINE** edited by George Schlager Welsh and E. Grant Dahlstrom. 336 pages. University of Minnesota Press, Minneapolis, Minn., 1956. Price \$8.75

The Minnesota Multiphasic Personality Inventory (MMPI) is a multi-variate personality instrument which is currently one of the most widely used questionnaires and one of the best empirically constructed scales. Ever since its introduction 15 years ago a tremendous amount of effort has been expended in constructing and attempting validation not only of the original MMPI scales but also of some 100 additional scales. The editors of this collection of articles, a psychologist and psychiatrist, both members of the departments of psychology and psychiatry, have rendered a good service to students of human behavior, amateur or professional, by bringing together in book form these basic readings on the MMPI in psychology and medicine.

Of the 699 articles on the MMPI arranged in a master list in the bibliography and complete through December 1954, the editors chose 10 per cent (66 articles by 43 authors) of those they considered to be the most important as the basis of this book. Selections were difficult to make and compromise was necessary to pick articles that would be most serviceable to psychologists and psychiatrists as well as to clinicians, research workers, and students of personality test construction and theory. Preference was given to publications having historical priority, completeness of analysis, sample representativeness, or imaginative design. Over half of the 699 MMPI items have appeared in the years since 1950. The articles chosen range over the years from 1940 through 1954 and include three original papers prepared especially for this book.

The book presents evidence of the urgent need, when using the MMPI and other diagnostic tools, for obtaining necessary validating estimates required in personality measurement. In clinical practice we find that the MMPI scale scores indicate possible areas of maladjustment by sorting profiles according to their highest abnormal T scale scores. Users of the MMPI or its 100 other scales will find this book indispensable. —FRANK ALLMAN, Jr., Lt Col USAF (MSC)

**TREATMENT OF HEART DISEASE: A Clinical Physiologic Approach** by Harry Gross, M.D. and Abraham Jeger, M.D. 549 pages, illustrated. W. B. Saunders Co., Philadelphia, Pa., 1956.

This book is different and it has a valuable place among textbooks for specialists in internal medicine and cardiology. The overall approach is one of adapting basic information very clearly and practically to effective treatment of patients with heart disorders either in office or within the hospital. The book includes discussions of practice, basic mechanisms of cardiac symptoms and management, hypertensive, inflammatory, and congenital heart disease problems, surgery in the cardiac patient, and diseases of the heart secondary to metabolic disorders. The concluding part deals realistically with the emotional problems of the patient with heart disease and his general life in his community.

This entirely new text was written primarily for practitioners of medicine but it includes a great deal of basic information of value to students as well as graduates in medicine. The viewpoints of other authorities and their interpretations are presented.

The double column format of this book makes it easy to read. For the student in cardiology who desires further details each chapter closes with a long list of references. This is not just another book but a really worthwhile contribution.

—U R MERIAANGAS Col MC USA

BRITISH MEDICAL BULLETIN Volume 12 Number 1 January 1956 Recent Research on Vitamins 90 pages illustrated Published by the Medical Dept The British Council London W1 England Distributed by Oxford University Press New York N Y Jan 1956 Price \$2.75

The January 1956 issue of the authoritative *British Medical Bulletin* is devoted to advances in vitamin research. Some of the most prominent names in British medicine are present and in keeping with their traditions the articles are short, clear, and pertinent. The subject matter includes the role of vitamins in vision, bones, skin, and nervous system as well as such topics as the effects of food processing, antivitamin, and lipotropic agents. These articles serve as an excellent current survey and as a helpful reminder that much remains to be done in the field of vitamin nutrition. —S O WAIFE Lt Comdr MC USNR

AN ATLAS OF ANATOMY by J. C. Boileau Gant M C M B Ch B F R C S (Edin.) 4th edition 8½ by 11 inches in size 556 pages 714 figures in color arranged in the regional manner The Williams & Wilkins Co Baltimore Md 1956 Price \$15

This atlas has earned a secure place among basic anatomy volumes and the improvements added to this edition further enhance its value and function.

Many of the old illustrations have been improved, some enlarged, and some deleted, and there are 80 new figures. The new additions include cross sections of the limbs and neck, orbital and nasal cavities, basic diagrams of the arteries of the upper and lower limbs, and many others. Other basic diagrams clearly depict the scheme of motor distribution of the limbs, anatomic variants of the cystic duct and cystic and hepatic arteries, and variations in the pattern of the cutaneous nerves to the dorsum of the hand.

The format is simple and functional, and the index refers to figure numbers instead of pages, which directs one easily to the subject matter. The legends and footnotes include all practical facts.

This book is a one volume atlas and as such has adapted and condensed the illustrations to adequately and concisely cover the entire field. It is not presented as a surgical anatomy. Within these limitations this presentation has achieved its purpose and should retain a high listing among such books. —RALPH M. MUGRAGE Capt MC USN

## SARCOIDOSIS

Treatment With ACTH and Cortisone

JOHN Q THOMPSON, Major MC USA

**A**LTHOUGH various medications have been employed, there is no known satisfactory treatment for sarcoidosis. Contraversial results have been reported from the use of corticotropin (ACTH) and cortisone. In 1950, Thorn and his co workers<sup>1</sup> mentioned that a patient with sarcoidosis did not improve with ACTH therapy. Their findings prompted Sones and associates<sup>2</sup> to publish a preliminary report proclaiming the favorable response of patients with sarcoidosis to ACTH. Subsequently, several reports on the treatment of sarcoidosis with the steroid hormones have appeared in the literature, and the majority of these publications indicate that these drugs exert a favorable effect on the course of the disease.<sup>3-12</sup>

By reporting 11 additional cases of sarcoidosis treated with ACTH and/or cortisone, we hope to aid in the evolutionary evaluation of an obscure disease treated with little understood compounds. The 11 cases represent a range in manifestations from apparent pulmonary disorders with no subjective symptoms to incapacitating symptoms of various types.

### CLINICAL INVESTIGATION

The study concerned patients with sarcoidosis who were admitted to this hospital during the period 1952 to 1954. Only those patients who showed no improvement, or who showed an increase in sarcoid manifestations while on a regimen of bed rest, were chosen for steroid hormone therapy. (These patients remained on bed rest while undergoing diagnostic studies.) In each instance,

From U S Army Hospital, Camp Pickett Va. Dr Thompson is now with  
ment of Internal Medicine of the Scott and White Clinic Temple Tex

a complete case history and physical examination were recorded. Any suggestion of tuberculosis, diabetes mellitus, cardiovascular renal disease, or neuropsychiatric abnormality which might contraindicate the use of the steroid hormones was noted. Routine clinical investigation included a complete hematologic examination plus determinations for chemical constituents as serum proteins (with albumin globulin ratio), blood urea, blood glucose (fasting) and serum calcium. Urinalysis and roentgenogram of the chest and a biopsy of all organs suspected of having sarcoid involvement. When indicated, bone marrow and cerebrospinal fluid examinations and specific tests for liver and renal function were done. For most patients an ophthalmoscopic examination was performed by a qualified ophthalmologist.

Table 1 gives brief historical and diagnostic data for the series of 11 male patients. Nine patients were Negroes and two were white. Ages ranged from 21 to 35 years. Although one patient (case 8) denied any symptoms, subjective symptoms varied with organ involvement. All patients had some pulmonary manifestations (mediastinal lymph nodes, parenchymal involvement or both) but predominant chest complaints were recorded in only three instances.

The final diagnosis was based upon the clinical picture, characteristic roentgen appearance of the lungs, hyperglobulinemia, and biopsy specimens showing tissue changes consistent with sarcoidosis. Although the biopsy specimens revealed normal tissue, the clinical picture and roentgen appearance of the lungs were so typical of sarcoidosis in three patients that the diagnosis was considered justified. Certainly in the diagnosis of sarcoidosis, reliance should be placed on biopsy specimens whenever possible, however, as explained by Sones and associates<sup>2</sup> and Israel and Sones,<sup>3,4</sup> the character of the sarcoid granuloma is nonspecific and the microscopic demonstration of epithelioid tubercles in surgically excised specimens is in itself not sufficient to establish a diagnosis.

#### TREATMENT

In order to individualize treatment, no particular rule was established for selecting ACTH or cortisone therapy. In general, a daily dosage of 25 mg of ACTH in 1,000 ml of 5 per cent glucose was administered intravenously over an eight hour period. Cortisone (300 mg on the first day, 200 mg on the second day, and 100 mg daily thereafter) usually was administered intramuscularly. Hormone therapy was continued until a response was obtained or it became evident that no response would occur. Then cessation of therapy was by gradual reduction of the dosage. Patients were given a regular diet with no added salt. Supplementary potassium was not prescribed routinely. Patients were weighed daily and daily blood pressure determinations were made.

Table 2 shows the established duration of illness prior to the institution of ACTH and cortisone therapy and the duration and results of treatment. The length of the treatment period was based chiefly on the degree of the patient's response, those patients whose response was slight or partial received continued medication in an attempt to effect further regression. When it became evident that no further improvement was likely to result treatment was discontinued.

Ten of the 11 patients treated with ACTH and steroid hormones showed some definite signs of improvement. (Improvement was based on roentgen demonstration of prompt and/or definite regression of pulmonary lesions, or by definite diminution in some of the objective manifestations of sarcoidosis.) When improvement occurred it usually was evident within a week. In many instances, response was so prompt that it seemed to be a significant factor in differentiating the results of treatment from a natural remission. Also, it was observed that recurrences or recrudescences often were evident as soon as 30 days after the cessation of therapy. Impressions gained from the very short term periods of observation indicated that pulmonary parenchymal and lymph node involvement seemed to recur early, whereas, ocular lesions and parotid and lacrimal gland involvement seemed to show more sustained improvement. Some patients received a second course of therapy.

No attempt was made to compare the effects of ACTH versus cortisone therapy. In case 4, it seemed that no reaction whatever was obtained from ACTH, however, the patient did improve with cortisone therapy. No studies were performed to ascertain if an adrenocortical response to ACTH was obtained.

One patient (case 11) received the largest total dosage of cortisone, but no objective signs of improvement or of progression were observed. Chloroquine phosphate, para aminosalicylic acid (PAS), and streptomycin sulfate were administered also.

Case 3 was interesting, because it seemed that this patient's symptoms of polydipsia and polyuria might represent sarcoid involvement of the pituitary gland. ACTH therapy was administered and the patient showed marked subjective improvement with roentgenographic evidence of regression of his pulmonary lesions but no regression of the symptoms of diabetes insipidus. Although ACTH did not alleviate the diabetes insipidus, he was maintained on Pitressin (brand of posterior pituitary pressor and antidiuretic hormone). Unfortunately, as with all of the cases studied, prolonged follow up information was impossible.

Two instances of possible toxic reaction deserve consideration. One patient (case 11) developed such marked subjective improvement that the possibility of euphoria (due to cortisone) was believed to be a factor, however, in .

a complete case history and physical examination were recorded. Any suggestion of tuberculosis, diabetes mellitus, cardiovascular renal disease, or neuropsychiatric abnormality which might contraindicate the use of the steroid hormones was noted. Routine clinical investigation included a complete hematologic examination plus determinations for chemical constituents as serum proteins (with albumin globulin ratio), blood urea, blood glucose (fasting) and serum calcium. Urinalysis, a roentgenogram of the chest and a biopsy of all organs suspected of having sarcoid involvement. When indicated, bone marrow and cerebrospinal fluid examinations and specific tests for liver and renal function were done. For most patients, an ophthalmoscopic examination was performed by a qualified ophthalmologist.

Table 1 gives brief historical and diagnostic data for the series of 11 male patients. Nine patients were Negroes and two were white. Ages ranged from 21 to 35 years. Although one patient (case 8) denied any symptoms, subjective symptoms varied with organ involvement. All patients had some pulmonary manifestations (mediastinal lymph nodes, parenchymal involvement, or both) but predominant chest complaints were recorded in only three instances.

The final diagnosis was based upon the clinical picture, characteristic roentgen appearance of the lungs, hyperglobulinemia, and biopsy specimens showing tissue changes consistent with sarcoidosis. Although the biopsy specimens revealed normal tissue, the clinical picture and roentgen appearance of the lungs were so typical of sarcoidosis in three patients that the diagnosis was considered justified. Certainly in the diagnosis of sarcoidosis, reliance should be placed on biopsy specimens whenever possible; however, as explained by Sones and associates<sup>2</sup> and Israel and Sones,<sup>11</sup> the character of the sarcoid granuloma is nonspecific and the microscopic demonstration of epithelioid tubercles in surgically excised specimens is in itself not sufficient to establish a diagnosis.

### TREATMENT

In order to individualize treatment, no particular rule was established for selecting ACTH or cortisone therapy. In general, a daily dosage of 25 mg of ACTH in 1,000 ml of 5 per cent glucose was administered intravenously over an eight hour period. Cortisone (300 mg on the first day, 200 mg on the second day, and 100 mg daily thereafter) usually was administered intramuscularly. Hormone therapy was continued until a response was obtained or it became evident that no response would occur. Then cessation of therapy was by gradual reduction of the dosage. Patients were given a regular diet with no added salt. Supplementary potassium was not proscribed routinely. Patients were weighed daily and daily blood pressure determinations were made.

Table 2 shows the established duration of illness prior to the institution of ACTH and cortisone therapy and the duration and results of treatment. The length of the treatment period was based chiefly on the degree of the patient's response, those patients whose response was slight or partial received continued medication in an attempt to effect further regression. When it became evident that no further improvement was likely to result, treatment was discontinued.

Ten of the 11 patients treated with ACTH and steroid hormones showed some definite signs of improvement (improvement was based on roentgen demonstration of prompt and/or definite regression of pulmonary lesions, or by definite diminution in some of the objective manifestations of sarcoidosis). When improvement occurred, it usually was evident within a week. In many instances, response was so prompt that it seemed to be a significant factor in differentiating the results of treatment from a natural remission. Also, it was observed that recurrences or recrudescences often were evident as soon as 30 days after the cessation of therapy. Impressions gained from the very short term periods of observation indicated that pulmonary parenchymal and lymph node involvement seemed to recur early, whereas, ocular lesions and parotid and lacrimal gland involvement seemed to show more sustained improvement. Some patients received a second course of therapy.

No attempt was made to compare the effects of ACTH versus cortisone therapy. In case 4, it seemed that no reaction whatever was obtained from ACTH, however, the patient did improve with cortisone therapy. No studies were performed to ascertain if an adrenocortical response to ACTH was obtained.

One patient (case 11) received the largest total dosage of cortisone, but no objective signs of improvement or of progression were observed. Chloroquine phosphate, para-aminosalicylic acid (PAS), and streptomycin sulfate were administered also.

Case 3 was interesting, because it seemed that this patient's symptoms of polydipsia and polyuria might represent sarcoid involvement of the pituitary gland. ACTH therapy was administered, and the patient showed marked subjective improvement with roentgenographic evidence of regression of his pulmonary lesions but no regression of the symptoms of diabetes insipidus. Although ACTH did not alleviate the diabetes insipidus, he was maintained on Pitressin (brand of posterior pituitary pressor and antidiuretic hormone). Unfortunately, as with all of the cases studied, prolonged follow up information was impossible.

Two instances of possible toxic reaction deserve consideration. One patient (case 11) developed such marked subjective improvement that the possibility of euphoria (due to cortisone) was believed to be a factor, however, in most patients showing

5	5	475	19	21	21	Marked improvement of lung and parathyroid glands on cortisone No marked improvement with complete clearing of eye lesions of ACTH therapy
6	3	420	20	10	10	Delayed improvement of lung and parathyroid glands and lacrimal glands Elevation of prednisone level with improvement of second course of cortisone but no improvement of pulmonary manifestations

limited experience of treatment with these drugs tends to support this belief

It is worth emphasizing that a diagnosis of sarcoidosis should be well established and differentiated from acute interstitial pulmonary fibrosis prior to the institution of steroid hormone therapy. Peabody and associates<sup>17</sup> reported that withdrawal of these drugs might prove harmful to patients with acute interstitial pulmonary fibrosis (Hamman Rich syndrome)

#### SUMMARY

Eleven patients with sarcoidosis were treated with ACTH and/or cortisone. Pertinent clinical and laboratory data were obtained to establish the diagnosis prior to institution of therapy. Ten of the 11 patients treated with steroid hormones showed some definite signs of improvement, although probably temporary. The aim of treatment should be to maintain the patient until a stage of natural remission occurs.

improvement there was an associated sense of well being. The other patient (case 6) had an episode of hematemesis during the second course of cortisone therapy. This may have represented a toxic reaction to cortisone manifested by gastric or duodenal ulceration or it may have been due to sarcoid involvement of the stomach and/or gastro-intestinal tract.<sup>11</sup> Roentgen studies (employing barium) made eight days after the episode of hematemesis failed to demonstrate any abnormality of the stomach or small bowel.

## DISCUSSION

Of the various substances employed in the treatment of sarcoidosis ACTH and the steroid hormones seem to offer the most promise. Although Hodgson and Woolner<sup>1</sup> stated that "most of the good results from therapy are limited to clinical response with little or no alteration in the x ray picture of the lungs," there was roentgenographic evidence of very definite regression of the pulmonary manifestations in most of our patients. Other workers have observed histologic changes in lymph nodes. Siltzbach<sup>4</sup> studied 13 post treatment biopsy specimens from 8 patients and noted slight to marked regressive changes in 10 specimens. Miller and Bass<sup>5</sup> reported a case concerning a patient who had progressive manifestations of sarcoidosis (proved by lymph node biopsy) for two years prior to treatment and response from ACTH. In this case the lymph node biopsy performed after therapy showed an absence of sarcoid involvement and the presence of extensive hyaline changes. Berger and Reiman<sup>6</sup> reported a case of sarcoidosis with renal involvement. Following steroid hormone therapy their patient showed clinical improvement of pulmonary and lymph node manifestations, but histologic studies of the kidney performed before and after treatment showed no change.

Thorn and associates<sup>7</sup> touched upon several important general considerations concerning the use of ACTH and steroid hormones which still seem to be applicable. (1) The physician employing these agents must possess a sound understanding of the multiple metabolic activities of these hormones. (2) the course of therapy undertaken with these agents must be truly individualized, (3) should the clinical response to ACTH administration be inadequate the production of an adrenocortical response should be verified and (4) the decision to employ chronic hormone therapy demands a comparative evaluation of the potential gains and risks involved. On this latter point Israel and Sones stated "It is our belief at present that treatment with cortisone is indicated in patients whose sarcoidosis appears to be recent and fresh. Treatment does not appear to be warranted in patients with chronic disease and few symptoms while a trial of these drugs is advisable in patients with ocular lesions, with pulmonary insufficiency or other manifestations of progressive disease." Our

rather dramatically re-emphasized by Fnos, Holmes, and Bever,<sup>3,4</sup> who reported pathologic studies of the coronary arteries of 200 soldiers killed in Korea. They found coronary disease of significant degree in 77 per cent of those men and severe atherosclerotic change in over 15 per cent. Their average age was 22.1 years, height, 5 feet 7 $\frac{1}{2}$  inches, and weight, 145.8 pounds.

In 1937 Benson<sup>5</sup> stated, "This condition is rare under 30 years and relatively uncommon under 40. To those of us who examine men periodically, prophylactically so to speak, to determine their fitness to fly, the early detection of coronary artery disease is a distinct problem." Today coronary artery disease has become much more commonly recognized in the young, but the problem and its solution remain unchanged nearly 20 years after publication of Benson's article.

### CLINICAL MATERIAL

One hundred and seven patients who suffered myocardial infarction were hospitalized at this base during the five year period terminating 31 December 1955. Eighty-seven of these were members of the military service on active duty. The remainder were retired personnel or dependents of active duty personnel.

**Age.** Table 1 gives the age distribution of the 107 patients. The age range for military personnel was 24 to 60 years. Of the 9 patients aged 60 to 82 years, 6 were dependents, 1 was retired, and 2 were on active duty.

TABLE 1 Age distribution of patients with myocardial infarction

Age group (years)	Civilians		Military personnel		Totals
	Male	Female	Active	Retired	
24-29	0	0	5	0	5
30-39	0	0	30	3	33
40-49	0	2	40	1	43
50-59	2	2	10	3	17
60-69	2	1	2	1	6
70-79	0	2	0	0	2
82	1	0	0	0	1
Total	5	7	87	8	107

**Sex, Race, and Status.** One hundred and two patients were white and five were Negro. One hundred were male and seven were

# MYOCARDIAL INFARCTION IN A MILITARY POPULATION

PHILIP G. KEIL, *Lieutenant Colonel, USAF (MC)*  
LEON V. McVAY, Jr., *MD*

**M**YOCARDIAL INFARCTION has a more serious connotation in the military services than in the general population. To maintain a combat ready force and necessary support elements physical standards must remain high and personnel with history of infarction are likely to be considered unfit for active duty.

Master Jaffe and Dack<sup>1</sup> estimated in 1939 that over one million myocardial infarctions occurred annually in the United States. Since then there has been a greater increase in the frequency of its occurrence than in the population and it is reasonable to assume that there is an increased incidence in the armed services.

In the Army and Air Force an electrocardiogram is required as a part of the annual physical examination of officers 40 years of age and over. We were surprised in the recent past at the number of men whose initial tracings showed unequivocal evidence of previous infarction. In taking the medical history of these men it was possible to date the attack in approximately half of the cases. This observation provoked our investigation of the problem of myocardial infarction in a military population.

We reviewed the clinical records of patients hospitalized with myocardial infarction at this base during the five-year period 1951 through 1955 inclusive. We were particularly interested in advanced coronary artery disease in younger persons and in the retainability of military personnel in the service after infarction.

Attention was focused on coronary artery disease in the young in 1948 by Yater and associates<sup>2</sup> who reported 886 cases in patients under 40 years of age (18 to 39 years). This was

Read before the Section on Military Medicine at the annual meeting of the American Medical Association, Chicago, Ill., 11-16 June 1956.

From U. S. Air Force Hospital, Maxwell Air Force Base, Ala. Col. Keil is now assigned to U. S. Air Force Hospital, Lackland Air Force Base, Texas.

Required in the Army for all flag officers, and for other personnel when indicated.

ing state, 10 were exerting themselves mildly to moderately, 5 were exerting themselves strenuously, and in 6 this information was unknown.

**Family History** Family history was negative in 24 patients, positive in 45, and unknown in 18. Family history was negative in 11 of all the patients under 40 years of age, positive in 20, and unknown in 7. In the individuals under 30, the family history was negative in 1, positive in 3, and unknown in 1.

**Type of Infarction** There were 29 posterior myocardial infarctions and 50 anterior infarctions, including septal and lateral, 3 individuals had both anterior and posterior infarctions, and in 5 persons the type was unknown. In all patients under 40, 15 had posterior infarcts, 21 had anterior, 1 had both, and in 1 the type was unknown.

**Use of Tobacco** There were only 2 documented nonsmokers in the series. Ten smoked moderately, that is, less than a package per day. Sixty smoked heavily, that is, more than a package per day, and usually one and one half to two packages. In 15, complete information was lacking. In all patients under 40, there were 2 nonsmokers, 9 moderate smokers, 17 who smoked heavily, and in 10 this information was not recorded.

**Use of Alcohol** There were 6 patients who did not drink, 50 who drank moderately, 16 who drank heavily, and 15 on whom this information was not recorded. In all patients under 40, 5 were nondrinkers, 20 imbibed moderately, 4 heavily, and in 9 this information was not recorded.

**Severity of Infarct** Twelve were classified as mild, 28 moderate, 24 moderately severe, and 23 severe. In all patients under 40, 5 were considered mild, 15 moderate, 11 moderately severe, and 7 severe.

**Outcome** Fifty of the 87 military patients were retired from active duty following their initial infarction with disability ratings of from 60 to 100 per cent (average rating 80 per cent). Thirteen military patients died and 24 were returned to active duty. In only one instance was an individual returned to active duty by the Physical Evaluation Board after the Medical Board had recommended retirement. Of the civilian and retired group, 3 retired military personnel and 2 civilians died, 5 retired military personnel and 10 civilians survived.

## DISCUSSION

Our primary interest in collecting these data was to investigate the outcome of the cases and find the number of persons who returned to effective military duty. Secondly we were interested in clinical features, age groups, habitus, habits, etc.

female. All of the females were dependents. Eighty seven were active duty personnel, 8 were retired, and 12 were dependents.

**Seasonal Incidence.** Most of the infarctions occurred during spring and summer, contrary to many reported series and general belief. The occurrence by months is given in table 2. It was not possible to determine accurately the month of infarction in five of the civilian patients, since the unrecognized infarction had occurred previously, and the patient had been referred to this hospital for treatment of residuals.

TABLE 2 *Month of occurrence of myocardial infarction among 107 patients*

Month	Number of patients	Month	Number of patients
January	3	July	8
February	3	August	15
March	11	September	7
April	16	October	9
May	14	November	3
June	8	December	5
		Unknown	5

**Body Build.** Body build was determined only on active duty military personnel according to the height weight standards cited by Duncan.<sup>4</sup> Forty seven were obese, 28 were within the average range, 7 were underweight, and in 5 this information was lacking. In all patients under 40 years of age, 17 were obese, 14 were average, 4 were underweight, and in 3 this information was unknown.

**Angina.** Of the 87 persons on active duty, a history of angina was present in 27, absent in 52, and undetermined in 8. In all patients under 40 years of age, angina was present in 9, absent in 25, and undetermined in 4.

**Hypertension.** A moderate degree of hypertension was present in 15, 66 were normotensive, and in 6 this information was not available. In all patients under 40 years of age, 4 were hypertensive, 31 normotensive, and in 3 this information was lacking.

**Predisposing Factors.** With reference to physical activity at the time of infarction, the following pertains: 20 patients were sleeping, 30 were awake but in a resting state, 19 were mildly to moderately active, 6 were performing strenuous physical exercise, and in 12 this information was lacking. Among all patients under 40 years, 8 were sleeping, 9 were awake in a rest

ing state, 10 were exerting themselves mildly to moderately, 5 were exerting themselves strenuously, and in 6 this information was unknown.

**Family History** Family history was negative in 24 patients, positive in 45, and unknown in 18. Family history was negative in 11 of all the patients under 40 years of age, positive in 20, and unknown in 7. In the individuals under 30, the family history was negative in 1, positive in 3, and unknown in 1.

**Type of Infarction** There were 29 posterior myocardial infarctions and 50 anterior infarctions, including septal and lateral, 3 individuals had both anterior and posterior infarctions, and in 5 persons the type was unknown. In all patients under 40, 15 had posterior infarcts, 21 had anterior, 1 had both, and in 1 the type was unknown.

**Use of Tobacco** There were only 2 documented nonsmokers in the series. Ten smoked moderately, that is, less than a package per day. Sixty smoked heavily, that is, more than a package per day, and usually one and one half to two packages. In 15, complete information was lacking. In all patients under 40, there were 2 nonsmokers, 9 moderate smokers, 17 who smoked heavily, and in 10 this information was not recorded.

**Use of Alcohol** There were 6 patients who did not drink, 50 who drank moderately, 16 who drank heavily, and 15 on whom this information was not recorded. In all patients under 40, 5 were nondrinkers, 20 imbibed moderately, 4 heavily, and in 9 this information was not recorded.

**Severity of Infarct** Twelve were classified as mild, 28 moderate, 24 moderately severe, and 23 severe. In all patients under 40, 5 were considered mild, 15 moderate, 11 moderately severe, and 7 severe.

**Outcome** Fifty of the 87 military patients were retired from active duty following their initial infarction with disability ratings of from 60 to 100 per cent (average rating 80 per cent). Thirteen military patients died and 24 were returned to active duty. In only one instance was an individual returned to active duty by the Physical Evaluation Board after the Medical Board had recommended retirement. Of the civilian and retired group, 3 retired military personnel and 2 civilians died, 5 retired military personnel and 10 civilians survived.

## DISCUSSION

Our primary interest in collecting these data was to investigate the outcome of the cases and find the number of persons who returned to effective military duty. Secondly we were interested in clinical features, age groups, habitus, habits, et cetera.

This group varies little from other series as regards mortality family history, antecedent history of angina, hypertension, body build and smoking and drinking. As a rule the younger individuals had previously been athletically inclined and in robust health. They attained a grade commensurate with supervisory positions and sedentary habits, gained weight and smoked and drank more. Most suffered their infarcts without a period of progressive angina and while they were physically idle.

It was apparent from study of this group of patients that the diagnosis of myocardial infarction is not entertained as early or as seriously in the young patient as in the older one. Diagnoses such as spontaneous pneumothorax, acute serofibrinous pericarditis, pleurodynia and gastroenteritis are frequently considered first. Fortunately the almost routine use of the electrocardiogram in the differential diagnosis of chest and epigastric pain has done much to correct erroneous first impressions.

We were unable to obtain an accurate follow up on the 24 military personnel who returned to active duty. We do know that a number of the 50 who were retired had first been sent on a "trial of duty" for a few weeks or months. Why were they unable to perform sedentary duties? In general we found that they were not considered acceptable for retention by medical officers. Often if the ex-patient complained of the slightest symptoms referable to the heart and related to the physician his history of hospitalization for a myocardial infarction, he was returned to patient status with a recommendation for action by a Physical Evaluation Board. Many patients were told that they would be retired after due hospitalization and might expect a high percentage of physical disability retirement.

A simple solution of the problem would be to retire all persons with myocardial infarction, however we are trying to retain highly motivated and skilled personnel despite borderline physical defects. Obviously if we are to return any of these individuals to active duty military physicians must take a more receptive attitude toward their retention and must appreciate the difference between "fully qualified" for active duty and "acceptable for retention" on active duty.

We believe that definite criteria should be established for retainability after myocardial infarction unless we agree that all should be retired. What should the criteria be? Let us first itemize those findings which would preclude return to duty of those surviving a first infarction irrespective of age: (1) serious disturbance of cardiac rhythm (2) significant cardiomegaly (3) cardiac failure (4) prolonged shock (5) recalcitrant angina (6) incapacitating dyspnea and (7) serious thromboembolic complications.

There remains a group of individuals who have none of these, but who did have, unmistakably, a myocardial infarct. These people recover completely, are asymptomatic on moderate activity, and have a normal sized heart and normal circulation. We believe these persons should be retained on active duty, because many are well qualified and motivated noncommissioned and commissioned officers. Such a policy, if put into effect, should be publicized to medical personnel, and these people should not be treated as invalids after return to duty. We are inclined to agree with Walker,<sup>7</sup> who concluded "To restrict the activity of a patient who has survived myocardial infarction without residual cardiac or coronary insufficiency probably shortens his actual survival and surely shortens his useful life."

The decision regarding return to flying status is extremely important to those previously on flying duties. We believe that, after six months from the date of infarction, if cardiovascular examination is normal and the individual asymptomatic, he could be returned to flying status as a crew member not in primary control of the aircraft, or as a pilot in primary control in a dual control aircraft with another qualified pilot. This, of course, is our opinion derived from a strictly medical point of view, and has no inference as far as Air Force policy or suggested policy is concerned.

Since the report by Benson in 1937 of a pilot sustaining a coronary thrombosis while flying, there have been several similar instances recorded in military and civilian pilots. Although thrombosis occurs most often during the sleeping and resting state, it is reasonable that chance alone would dictate its occasional occurrence while flying. When one ponders the number of people with advanced coronary disease who fly in commercial and private aircraft, and considers the fact that a small amount of hypoxia may occur in flight even in pressurized aircraft, it is amazing that coronary thrombosis in flight is not rather commonplace.

#### SUMMARY

One hundred and seven patients were treated for myocardial infarction at this base in the five year period ending 31 December 1955. Fifty seven of these were active duty military personnel, 8 were retired personnel, and 12 were civilians.

Thirty eight infarctions occurred in patients below the age of 40. Most of the 107 infarctions occurred during the summer months, while the patients were sleeping or resting. They usually occurred without a history of angina in individuals who were nonobese but inclined to be obese, who smoked heavily, drank moderately, had a sedentary job, and had a family history of cardiovascular disease.

Thirteen of the 87 active duty military personnel died as a result of infarction 24 returned to duty and 50 were retired with an average disability rating of 80 per cent

We believe that those individuals suffering relatively mild myocardial infarction without objective or subjective sequelae should be returned to duty This will require intelligent management by base medical personnel to eliminate unnecessary referral of persons with only slight or equivocal symptoms for hospitalization and evaluation

#### PAGING PATHOLOGISTS

The acute shortage of pathologists is an ever-recurring topic at national medical meetings. It is estimated that the total number of pathologists in the United States should be doubled to meet the needs of practice, teaching, and research. More and more hospitals have been adding pathologists to their staffs since World War II. The recognition of the important role of the pathologist in clinical medicine and resident training has placed the pathologist in a strategic position of great demand. Many new research programs involve studies in pathology. The military services which have trained essential large forces in this country and require pathologists

# PRESERVED ERYTHROCYTES IN Rh ANTIBODY TESTING

FRANK W. CHORPENNING *Lieutenant Colonel MSC USA*

ALLEN A. YOUNG *Sergeant First Class USA*

RAYMOND W. BOUDREAU *Sergeant USAR*

**I**N erythrocyte testing, especially in Rh typing, it has long been axiomatic that fresh cells should be used. Hattersley and Fawcett<sup>1</sup> and Wall, Jynne, and Benuchamp<sup>2</sup> have recommended the use of cell suspensions preserved in a manner similar to that used for sheep cells in the complement fixation<sup>3</sup> and heterophil procedures. Even though this would be helpful in solving problems of cell procurement and test variability, recently published methods of Rh antibody testing still specify the use of fresh cells as a source of antigen.<sup>4,5</sup>

In view of the foregoing, and since preserved cell preparations have become available commercially, wider acceptance of this method appears indicated. Therefore, the following data are presented as further confirmation of the feasibility of using such preserved cells for Rh antibody titrations.

## METHODS

The modified Alsever's solution contained 2.05 per cent dextrose, 0.8 per cent sodium citrate, 0.42 per cent sodium chloride, and 0.055 per cent citric acid in doubly distilled water. This was dispensed in bottles with rubber caps and sterilized by autoclaving. Blood to be preserved was injected aseptically into an equal quantity of the preservative solution. The bottle of preserved cells was then stored at approximately 6°C until required for use.

When cells for testing were desired, a portion was removed aseptically with a sterile syringe and 20 gage needle, after the surface of the rubber cap was swabbed with 70 per cent alcohol. These cells were then washed three times in physiologic saline solution and resuspended to a 2 per cent suspension in saline or albumin, as required for testing.

TABLE 2 *Titers of anti D serum pool with fresh and preserved cells Lo*

Blood specimen	No	Preservation period					
		1st week	2d week	3d week	4th week	5th week	6th week
Fresh	Lo 1	16 16	16 16	16 8	16 8	(16) 16	(16) 8
Preserved							
Fresh	Lo 2	16 16	16 16	16 8	(16) 16	(16) 16	(16) 8
Preserved							
Fresh	Lo 3	16 16	16 16	(16) 16	(16) 16	(16) 16	
Preserved							
Fresh	Lo 4	16 16	16 16	(16) 16	(16) 16		
Preserved							
Fresh	Lo 5	16 16	(16) 16	(16) 16	(16) 16		
Preserved							

Titers in parentheses were secured with fresh Yo cells in parallel testing

sequence of preservation Table 4 presents results of 27 different tests with these preserved cells against 9 different antisera produced in the course of maternal immunization. It can be seen from the repeat testing with different cell suspensions that preservation and incidental aging had no appreciable effect on cell reactivity during the period of observation. Also it is evident that the method is suitable for titrating agglutinins as well as for incomplete antibodies.

TABLE 3 Summary of titer variations against two anti D serum pools with preserved cell suspensions as compared with fresh cells

Cell	Fresh cells			Preserved cells		
	No change	Up	Down	No change	Up	Down
Cell Yo	55	1	3	70	5	2
Cell Lo	52	0	0	37	0	12
Cell Mo	5	0	0	14	0	0
Total	112	1	3	121	5	14

### DISCUSSION

The academic question remains as to whether slight effects of preservation can actually be detected. Therefore, the data were subjected to statistical analysis to determine the significance of observed differences between titers secured with fresh and preserved cells. Because they have a direct bearing on the results, differences in reactivity of different cells were also examined. For simplicity, results of tests with the first 10 cell suspensions (tables 1 and 2) were divided into two types of reactions: (a) no change in titer from the mode and (b) change in titer. This was considered valid because the large majority of tests yielded like titers for a given serum and because variations were no greater than one dilution from the mode. Table 5 shows these data for both fresh and preserved cells from donors Yo and Lo, tested against antiserum pool No. 1, and from donor Mo, tested against pool No. 2. The standard error of the difference between tests with fresh Yo cells and preserved Yo cells was 0.056, while the observed fractional difference was 0.040, leading us to conclude that the observed variation was due to chance. Similar comparison between fresh and preserved Lo cells yielded a significant difference, primarily due to decreases in titer. Most of these occurred in but 2 of the 25 cell suspensions. Therefore, it would appear probable that it was due to some factor not intrinsic to the preservation technique. There was no detectable difference between fresh and preserved Mo cell suspensions.

# DIFFERENTIATING BACTERIAL FROM VIRAL PHARYNGITIS AND TONSILLITIS

## A Rapid (Presumptive) Method

MONROE H. GREEN, M.D.

**T**HE PROBLEM of distinguishing pharyngitis and tonsillitis caused by bacteria (most commonly beta hemolytic streptococcus) from that caused by a virus is not always easy on purely clinical grounds.<sup>1</sup> Delay in starting penicillin therapy of streptococcal pharyngitis may permit sensitization of the patient to the organism or to its products with subsequent development of rheumatic fever or acute diffuse glomerulonephritis.

In the northeastern United States, approximately 75 per cent of the pharyngitis and tonsillitis encountered is caused by viruses with the remainder probably caused by beta hemolytic streptococcus.<sup>2</sup> Here in the Southwest, the prevalence of streptococcal infection may be lower; certainly it is not higher. Thus it is not rational to treat all patients with sore throats even those with exudate and cervical adenopathy with penicillin because of the risk of penicillin sensitivity reactions (1.2 per cent of patients treated with aqueous crystalline penicillin and 1.4 per cent or higher treated with repository types<sup>3</sup>). There is the further problem of creating penicillin fastness in normal pharyngeal saprophytes which may under rare conditions become pathogenic.

This study indicates that simple microscopic examination of tonsillar or pharyngeal exudate by direct smear may afford an accurate rapid diagnostic aid in differentiating bacterial (most commonly group A hemolytic streptococcal) from viral pharyngitis or tonsillitis.<sup>4</sup> The technic is neither new nor original but the test is more frequently omitted than used.

## MATERIALS AND METHOD

A study undertaken during the fall, winter, and early spring of 1955-1956 was made of 40 patients with clinical acute pharyngitis or tonsillitis with or without cervical adenitis. Their ages

---

Consultant in medicine and cardiovascular diseases, 3525th U. S. Air Force Hospital, Williams Air Force Base, Arizona. Dr. Green is now at 2021 North Central Ave., Phoenix, Arizona.

With the technical assistance of Mary T. Drake, B.S., A.S.C.P., A.S.M.T.

ranged from 12 to 68 years, with equal distribution of the sexes. As nearly as could be determined clinically, all were seen from 24 to 36 hours after onset.

After careful inspection of the throat, the exudate or reddened area was swabbed with a cotton applicator and the applicator rolled out gently on a glass slide. The slide was fixed in a Bunsen flame and Wright's stain applied as for a blood smear. This stain was used rather than Löffler's methylene blue because it would provide the added detail of differentiating eosinophilic from neutrophilic leukocytes and perhaps demonstrate an underlying or accompanying allergic pharyngitis. This technique usually demonstrates the predominant cell of the exudate. All patients with predominantly neutrophilic or eosinophilic leukocytes in the exudate were given three 500 mg (600,000 unit) doses of aqueous procaine penicillin G suspension intramuscularly—the first immediately, the second in 24 hours, and the third 36 hours after the first dose. The response to this therapy was measured by the speed with which fever, pharyngeal inflammation, and cervical adenopathy subsided and by the general condition of the patient after 24 hours of therapy.

Seven patients among those who had mononuclear cells predominating in their exudate were also given penicillin after throat cultures were obtained. These were selected at random, the purpose being to use the lack of response to penicillin as evidence of the viral origin of their infection, or, at least, of the absence of beta hemolytic streptococci as a causative agent.

## RESULTS

In 26 cases with polymorphonuclear neutrophils predominant in the exudate, 22 had positive cultures for beta hemolytic streptococci. In the remaining 4, this cellular response heralded a hemolytic staphylococcus infection.

All 22 patients with positive hemolytic streptococcus cultures and polymorphonuclear neutrophils in the smear made a good response to penicillin therapy, with rapid subsidence of all symptoms in from 12 to 36 hours. The 4 patients with hemolytic staphylococcus infections made a moderately good response, with subsidence of symptoms in 48 hours.

In contrast, 13 patients with mononuclear cells in their exudate showed no hemolytic streptococci or staphylococci in their cultures. One of these patients had acute infectious mononucleosis with a pharyngeal membrane and predominantly mononuclear cells on smear examination. Seven of the 13 were treated with penicillin but made no response and had a course identical with those treated purely symptomatically, with fever and sore throat lasting

One patient with predominantly mononuclear cells in the pharyngeal exudate had a positive culture for beta hemolytic streptococcus but received no penicillin. He fortunately developed no sequelae to his infection.

It should be emphasized at this point that the apparent predominance of streptococcal and staphylococcal sore throat in this series does not reflect the incidence in the community, out only in 40 patients with a variety of chronic pulmonary and cardiac conditions who presented themselves at the office for treatment of acute sore throat.

Other causes of polymorphonuclear neutrophilic pharyngeal exudates not encountered in this study include fusospirochetal infection, late complications of the common cold, late stages of viral pharyngitis and of course diphtheria which should always be kept in mind in the differential diagnosis of sore throat. Fusospirochetal pharyngitis usually responds well to penicillin as may the late bacterial complications of the common cold and viral nasopharyngitis. The latter two diseases were believed ruled out by history since all patients were seen within 24 to 36 hours after onset.

A source of error in this method of study is the fact that many viral infections such as the common cold or viral nasopharyngitis may be characterized in their late stages by a leukocytic response in the nasopharyngeal or pharyngeal exudate. At this stage they may also respond well to penicillin as a result probably of invasion by penicillin susceptible bacteria or coincidentally. An attempt to counter this error was made by selecting patients believed to have had sore throats of only 24 to 36 hours duration.

Another pitfall is the use of culture alone rather than in conjunction with serologic typing of the recovered streptococci. All pathogenic streptococci in the nasopharynx and pharynx are in group A and can be so classified only serologically.

About 1 or 2 per cent of normal adults harbor these organisms in their throats; these patients conceivably might have a viral pharyngitis yet yield pathogenic streptococci on culture and typing.<sup>3</sup> It is recognized therefore that the recovery of beta hemolytic streptococcus from the throats of patients with acute pharyngitis of short duration can be considered as only presumptive evidence of its causative relationship to the pharyngitis. Further delay in response to penicillin may occur in streptococcal infections but the criterion of speed of response was used not alone but in combination with other criteria listed and it is believed that it has some significance when considered in that light.

## SUMMARY AND CONCLUSIONS

A rapid, simple method for the presumptive diagnosis of hemolytic streptococcal sore throat is suggested that is easier than either differential white blood cell count or throat culture. It uses Wright's stain for study of a smear of pharyngeal exudate. If there is a predominance of neutrophils, the infection may be considered to be bacterial, probably streptococcal, and should be immediately treated with penicillin. If the exudate is predominantly composed of nucleolar or epithelial cells, the infection may be regarded as viral and antibiotic therapy withheld, at least until a culture is obtained.

This method was used in 40 patients with acute pharyngitis or tonsillitis, who were seen from 24 to 36 hours after onset of illness. Pharyngeal smears from 26 indicated the presence of bacterial infection, which was confirmed by culture. The 22 patients with beta hemolytic streptococcus showed a dramatic response to penicillin in 12 to 36 hours, and 4 with hemolytic streptococcus had a fair response to penicillin in 48 hours. Pharyngeal smears of 13 patients indicated the absence of bacterial infection. Cultures in this group did not grow beta hemolytic streptococcus, and 7 of the 13 were treated with penicillin without effect.

This series is a small one, but it is believed that the method deserves further study, using serologic typing of the organism recovered on culture and making certain, if possible, that one is not dealing with the bacterial complications of the common cold or viral nasopharyngitis, or with coincidental nasopharyngitis in a carrier of group A streptococci.

# DEVELOPMENTS IN SOCIAL PSYCHIATRY

## Observations in Five Selected English Hospitals

DENNIE L. BRIGGS *Lieutenant MSC USN*  
LINA STEARNS *Lieutenant Commander NC USN*

**F**OR MORE than a month we were fortunate in being able to spend full time with the staffs and patients of five unique English hospitals for the treatment of emotional disorders—hospitals selected as representative of the more recent trends in social psychiatry with emphasis on institutional management and treatment.\* We were interested in knowing about (1) the types of illness treated within the hospital setting (2) the actual process and extent of behavioral change and (3) the specific procedures that had evolved. We wanted to see what had been achieved by applying these techniques over a considerable period of time in order to better evaluate the psychiatric admissions program that was begun at this hospital by Dr. Harry A. Wilmer, following a visit to England a year ago. In less than one year the results of using these methods in a military setting had been more immediate and far reaching than anticipated considering that in the English hospitals these social psychiatric methods had been in use for 8 to 10 years and more.<sup>1-3</sup>

This report will describe our impressions of the five hospitals and discuss some of the areas and techniques that we believe will be of value in other hospital settings particularly within the armed services.

### BELMONT HOSPITAL

Fourteen days were spent in the Social Rehabilitation Unit of Belmont Hospital, in Sutton, south of London. The unit is housed in a building over one hundred years old, formerly used as a work house. It was badly blitzed during World War II and still shows

---

From U. S. Naval Hospital Oakland, Calif. Sponsored by the Neuropsychiatry Branch Bureau of Medicine and Surgery Research Project NM 007 090 21. Commander Harry A. Wilmer, MC, USNR, principal investigator. Lt. Briggs is now assigned to U. S. Naval Hospital Navy 3923, FPO San Francisco, Calif.

We wish to thank Sir Walter McClay and Doctors Maxwell Jones, T. P. Res Thomas, and Johanna Biele and their staff for time spent allowing us their treatment methods.

We are indebted to Dr. Louis Minsky and Miss Phyllis Arnold for arranging for us to live in during our stay in order to participate in the entire day (and night) of the patient's resocialization.

evidence of the bombings. The hospital is an open ward hospital of 400 patients, emphasizing physical treatment of the neuroses. The unit of about 100 male and female patients is run autonomously, but under the management of the hospital proper. Patients are referred to the unit from all parts of England by courts, physicians, and psychiatrists. They represent the various character and behavior disorders and some neuroses. Many are those traditionally referred to as "psychopaths," with social backgrounds replete with thievery, various types of addictions, sexual delinquency, and continual inability to make social and vocational adjustments. They are admitted for an undetermined time, however, the average stay is from four to six months, and no patients remain longer than a year.

The staff consists of the Medical Director, Dr. Maxwell Jones, three other psychiatrists, a head nurse (sister), two male staff nurses, a night nurse, a psychiatric social worker, a psychologist, four work shop instructors, two secretaries, and two domesticities. In addition, there are two Ministry of Labour Disablement Resettlement Officers (DRO's) who assist in obtaining employment for patients upon their discharge from the hospital.

The unit "is designed to help patients overcome their social fears and problems and to readjust to life outside." The idea of the therapeutic community originated nine years ago with Maxwell Jones from his experiences with rehabilitation of prisoners of war who needed to become resocialized before returning to their communities. "Similarly, patients in the unit needed comparable assistance in learning new values and ways of readjusting to society."

The fundamental aim in treatment is socialization of the patient, and the unit is designed to create a therapeutic atmosphere

where patients can (see) themselves as they really are. By so doing they can begin to learn to understand and if possible modify their behaviour through analysing their everyday relationships. Another aim of treatment is to give practical help in finding work and adjustment to the family outside."

The actual workings of the unit can perhaps best be described by the following account given by the sister:

At least one third of the day is spent in one group or another. It is here that the unit life differs from ordinary life for much of the treatment is based on trying to understand by talking freely the source of difficulty in relationships between people. The lessons learned in these psychotherapeutic groups are related to social life outside.

1 The whole community of patients and staff totaling about 120 people meets every morning from 8 30 to 9 45 a m. People sit where they like in a circle two or three deep. There is no formal chairman the doctor normally acts as timekeeper. Any topic can be discussed and raised by any patient or staff member. Thus the range of topics may include a discussion on drunken behaviour stimulated by an alcoholic s drinking bout the night before talking after lights out homosexuality pairing off complaints about the hot water system or missing light bulbs or criticism or praise of other patients and members of staff et cetera.

2 From 9 45 to 10 15 a m the patients have coffee in their cafeteria and the staff meet in the medical director s office for tea and a discussion on the meeting. An attempt is made to analyse and understand some of the various factors contributing to the tensions as seen in the previous meeting. In addition the staff meets twice a week for an hour to discuss and analyse staff tensions et cetera.

3 At 10 15 a m each doctor takes his patients in a therapeutic group. Three doctors have two groups of 45 minutes each. The other doctor prefers to treat all 25 patients in one group for one and one half hours.

4 After lunch each ward takes it in turn to have a weekly ward meeting from 12 30 to 1 p m. A doctor a sister social therapists and patients of the ward are present. Again any topic may be discussed.

5 The social therapists have a tutorial seven days a week with each member of the permanent staff in turn.

6 The instructors meet weekly to discuss workshop problems.

7 The domestic staff meets with the sister weekly to discuss domestic problems.

8 Every Wednesday a family group is held during visiting hours.

One of the unique forms of treatment is the work group to which each patient is assigned upon entering the unit. These work groups were created to give the patient opportunity to contribute to the maintenance of the unit in a meaningful way as well as to be therapeutic.

The activities include painting the interior of the hospital (the patients decide on the color of the paint to be used when a particular room will be painted and the manner in which it is to be painted) caring for the grounds of the unit and providing fresh

lowers for the hospital. The workshop group repairs and constructs furniture for the unit, the tailoring shop group makes and mends the patients' clothing, and the home group is responsible for cleaning the wards and other parts of the unit. Patients are required to spend a certain number of hours in the work groups and are assigned to keep a formal record of tardiness and absenteeism, which in turn is fed back to the entire community by name and by work group, thus providing for a spirit of competitiveness between the various work groups. The workshop instructors hold a weekly group meeting with the patients assigned to their particular group, and problems concerning work and interpersonal relations involved in the working situations are discussed and resolved.

There is an intensive program of social activities in the unit centering around a club room where nightly dances and other forms of social activities are run by the patients. Television is not permitted, because it would decrease socialization.

Efforts are made to extend the therapeutic process beyond the hospitalization of the patient, and along these lines a family group is held weekly composed of relatives who are interested in coming to the hospital to learn more about themselves and the patient, various staff members, and non-interested patients. This weekly group frequently includes as many as 50 members, and its success is measured in part by the frequent and regular visits of some of the relatives. An ex-patients' group meets one night per week at St. George's Hospital in London, where any former patient may come to talk about problems, renew old acquaintances, or gain courage to continue on in his daily life.

Much of the success of the treatment lies in the "social therapists," who are 11 young girls primarily from the Scandinavian countries and Holland. They have various backgrounds but usually are interested in one of the social sciences, like to be with people, and come to the unit for six to eight months to observe its functioning and to see the country. Their training, though informal, is intense consisting of afternoon tutorials seven days a week with the permanent staff. Here they are given a basic understanding of normal growth and development and opportunity to learn about interpersonal relations from their daily experiences with the patients. Current anxieties are thus used in a therapeutic manner through the daily tutorial, which carries through the basic concepts of the therapeutic community by extending its methods to the staff as well as to the patients. That the girls are foreigners seems to be advantageous, as the patient who cannot adjust to society also feels he is a stranger and can accept her more readily than an English girl who might have prejudices, even at an unconscious level, which would hinder the treatment process. Their role is to

son with whom the patient can learn techniques of social relations and in the treatment program they encourage communication and feedback between patients and between patients and staff.

### WARLINGHAM PARK HOSPITAL

This is a 1200 bed mental hospital in Warlingham Surrey, which is run entirely with open wards and treats all types of mental disorders including chronic schizophrenic patients. The hospital is located in the countryside of southern England, slightly isolated from even the nearest small community. All traditional types of psychiatric treatment are used here, including deep insulin coma electroshock psychosurgery (leukotomy) and the new tranquillizing drugs. The patients are admitted to two admission treatment units for male and female patients about 50 of each. They remain here until their illness has become stabilized and they are able to go on to other wards. Many leave the hospital directly from these units but some remain as long as three or four months on active physical treatment before moving on to another unit.

We were especially interested in the management of the more severely disturbed patients on open wards and visited two such "refractory" wards (one for males and one for females). The staff of the disturbed ward for approximately 40 male patients consisted of two male nurses and one female student occupational therapist (visitor from the Menninger Clinic).

One of the most impressive procedures at Warlingham Park is the use of patients in the treatment program. Alcoholic patients are successfully used as instructors for older psychotic patients teaching them crafts such as weaving crocheting et cetera.

One is continually impressed with the degree of therapeutic sophistication of the entire staff of the hospital. All personnel are thoroughly familiar with the aims of treatment and seem to be highly skilled in carrying them out in all situations. The role of the nursing staff has been considerably modified from that in most mental hospitals as the superintendent reiterated how he concentrated on meaningful occupations for the staff as well as the patients.

### CHAMPION HOUSE

This hospital is a lovely old English estate in the countryside some 10 miles from Warlingham Park. It has about 30 male and female patients who from a social and psychiatric standpoint are not considered ever able to be discharged from a mental institution. These patients have been hospitalized for a long time and have no family or friends to return to but are able to care for themselves within this type of setting to perform

normal tasks contributing to running the home. The staff of this unique hospital consists of a nurse and two or three domestic employees, and the major part of running the house and grounds is done by the patients.

Most of the patients have been hospitalized a good deal of their lives, one of the modern day tragedies of mental institutions. The driver who took us to the hospital remarked, "had we known 20 years ago the things about treatment we know today, these patients wouldn't be here." One patient had been hospitalized over 50 years.

### CASSEL HOSPITAL

Cassel Hospital is primarily for treatment of neuroses by intensive psychotherapy. It is an entirely open hospital, and physical treatment is not used. The orientation is psychoanalytic, and most of the permanent staff have had a high degree of training in psychoanalytic theory and technique. The head nurse is a qualified lay analyst, several other nurses have been analyzed, and one is an analytic candidate. The nurses do not wear uniforms or make ward rounds, but each has a specific function that is used therapeutically in working with the patients. Nurses are encouraged to work at tasks they enjoy doing, thus being models for the patients. One nurse, for example, enjoys sewing and keeps her machine in an easily accessible stair landing at the hospital. Patients may join her or drop by to visit. Through meaningful work which the nurse enjoys, the opportunity for social relations is extended in a manner which facilitates more rapid and complete recovery than could be achieved by a nurse in a white uniform seeing to keeping the ward in spotless order. Although the treatment is centered about individual intensive psychotherapy, the patients run the hospital to a large degree. Most practical matters in its administration are handled quite formally by committees, and decisions reached by the patients are carried through. The matter of patients' letters being stolen from the mailboxes was brought up by a committee of patients and staff. The larger community had decided that this was the staff's responsibility and that they should take steps to end the pilfering. When Dr. Main, the Medical Director, pointed out that the staff's responsibility ended legally when they accepted the mail from the post, the committee considered other means. Various methods were considered, including reporting the matter to the police and bringing in plain clothesmen. The staff deflected the responsibilities to the patient committee, who worked out a solution to ensure safekeeping of their mail, and this was taken back to the community for final approval.

One of the unique features of this hospital was the admission of the patient's husband or wife and children if necessary, based on the promise that emotional illness is nothing to keep

the family and that they may in fact aid in the treatment process. Some of the mothers have to bring their children as they have no means to provide for them while hospitalized. The entire atmosphere of the hospital was natural rather than institutional.

Education and training of the staff is stressed continually and at all levels. The program includes informal training through working under close supervision with a highly trained staff and formalized presentations of carefully developed theories of personality development but it always emphasizes the normal personality rather than abnormal states. In the summer a course is given for nurses outside the hospital dealing with growth and development and helping the nurse to see her role in relation to the patient's treatment.

### MARLBOROUGH DAY HOSPITAL

This institution bears little resemblance to a hospital in the usual sense of the word. It is located in London and treats about 100 patients who come to spend the day in intensive treatment and return to their families or homes at night. The underlying philosophy is that total hospitalization might be undesirable or even harmful by interfering with readjustment to society. An intensive treatment program includes individual psychotherapy, group psychotherapy, and recreational and occupational activities as well as social ones. There is an evening clinic for those patients who cannot receive treatment during the day because of their work schedules or who are reluctant to ask their employer for time off for fear he may not understand emotional illness and they might lose their jobs. Meeting crises with direct action thereby giving the patient hope and getting him into treatment sooner is used frequently in the practical approach by Dr. Joshua Bierer and his staff at this hospital.

The hospital maintains a large number of "social therapy clubs" in the London area and throughout the world for ex-patients and others to meet together socially and be provided an opportunity for treatment.

### DISCUSSION

In relation to the techniques developed by these five very different hospitals for treating emotional disorders certain principles seem paramount and pertain not directly to the use of social psychiatry in hospital treatment.

Elevation of the Role of the Patient. Respect for the dignity of the patient seems to be the most fundamental idea in the treatment programs of the hospitals we visited. Formerly the patient was regarded as "irresponsible," "dangerous," "psychotic," "neurotic," etc. etc. These terms designate their behavior as unacceptable and serve to isolate them from human contact. Traditional

mental hospitals further isolate patients because of the staff's inability to tolerate their behavior, thus the over use of physical therapy "quiet" rooms, sedation, restraints, and other forms of treatment often lightly disguised as being "for the good of the patient".<sup>11</sup> The patient's behavior is increasingly seen as purposeful and meaningful to him, and the principal task of the staff is first to be able to accept the behavior, no matter to what lengths the patient may go to encourage reprisal, and then to understand what the patient is trying to communicate to others. The symptom of his illness, while serving to isolate him from human society which he sees as distrustful and fearful can thus be used as the first step in his rehabilitation. When this process is understood, it is transmitted to other staff members and to the patients who actually carry out treatment according to their own abilities. It allows for the development of individuality in both patients and staff.

One of the initial impetuses for re-examination of the traditional roles of the staffs of mental hospitals was associated with the acute shortage of trained personnel following World War II. The whole idea of the patient-centered hospital involves the working through of staff anxieties regarding their own acceptance of the patient's socially unacceptable behavior.<sup>12</sup> Only as staff members are able to tolerate the patient's behavior can they feel comfortable enough to allow and encourage the "well part" of the patient to emerge. As staff members are better able to examine their own anxieties, feelings, prejudices, et cetera, toward unacceptable behavior patients become increasingly more responsible for running their own lives. This involves the often tremendously painful task of examining one's own behavior as well as the effectiveness of traditional hospital procedures.

The socialization process begins when the patient is allowed increased participation in the total treatment program by sharing in administrative decision making, as well as helping other patients—and staff. The change over from a more authoritarian atmosphere to one where staff members feel comfortable enough to give up some of the more suppressive elements of their roles is not an easy or smooth adjustment.<sup>13</sup> The hierarchic arrangement which the hospital fosters because of the wide divergence of training and experience of the various staff members must be critically examined when considering the establishment of an environment conducive to co-operation and mutual respect. For this reason, a continual education program is needed whereby new members can become acculturated and older members may continue to grow.<sup>14</sup>

**Communication and Feedback.** There appear to be two main where the patients contribute most to the treatment

the therapeutic community type hospital. These areas we may roughly designate as administration and actual treatment.

Assuming that patients often talk to each other more readily than to the staff it follows that patients often will more easily accept suggestions from other patients than from the staff. It would appear by staff patient communication to the point where the patient feels increasingly comfortable with the staff. Intimate contact between patients in this type of hospital setting often encourages the initial revelation of important and frequently disturbing thoughts and ideas to other patients. In other instances the patient feels comfortable in revealing such material only to staff members. The basic premise in the therapeutic community type of treatment is that both sources of communication will at one point or another be fed back to the entire community or to large segments of it. When the idea of free communication and feedback has been properly developed and used the patient's confidence may bring up the actual content of the material in the group or if he is a more skillful therapist will encourage the patient to appeal to the community for assistance and understanding of his behavior and thus attempt to arrive at acceptable solutions for his difficulty.

Insofar as staff members are able to allow patients to share in decision making the administration of this type of hospital also becomes therapeutic. The appeal to the group conscience becomes an enforcing agent and represents a highly developed type of social control which exercises the authority in a community. The degree of patient participation in administrative and therapeutic endeavors is perhaps most graphically illustrated by the extensive use of alcoholic patients in Warlingham Park Hospital. Here chronic alcoholics are used as therapists for older schizophrenic patients. They are assigned small groups of patients and work with them daily in various activities which they enjoy. As the alcoholic patient becomes increasingly more skillful in dealing with sicker patients he is beginning to regain self confidence and to develop a feeling of accomplishment in the total treatment program. In addition he receives group and individual psychotherapy for his own disorder. In such instances we see developed a more highly refined process of the concept which Stanton and Schwartz<sup>4</sup> have set forth as "administrative therapy".

**Training the Staff** In order to establish and perpetuate the fundamental ideals of a therapeutic community in a hospital setting there must be a means for indoctrination and continual growth of the staff members. By virtue of traditional medical training in a highly structured hierarchy certain aspects of roles and role expectations must be "unlearned". Since much of the suc-

ness of social psychiatric methods depends on the constantly changing nursing staff, a method of education and re education taking into account the staff's own dynamics, needs to be established. At the Social Rehabilitation Unit the use of "tutorials" has been found appropriate to the needs of the program. These are conducted seven days a week by a member of the permanent staff. The turnover of "social therapists" is frequent and their backgrounds varied. Thus their training must include a basic knowledge of people and a minimum of specific nursing techniques. The latter are taught by the nurse only as the situation arises, and the staff member then feels no pressure to be an expert on any phase of nursing. The nurse likewise can request assistance from the hospital proper if a specific nursing situation arises requiring specialized knowledge or techniques. Too often in their relationships with patients, psychiatric nursing personnel feel they must be able to deal with the patients in an unrealistic "therapeutic" manner. As the patient sometimes over identifies with the staff member in a transference situation, role expectations become confused and the staff member feels he must of necessity interpret the patient's behavior in order to help him. This is often coupled with the staff's own need to feel they are helping the patient in an active manner as formerly demanded in their medical training.

When making a transition from a traditional psychiatric hospital structure to a more "egalitarian" organization emphasizing understanding and dealing with interpersonal relations, attitudes of the staff must be closely scrutinized. As Jones and Rappaport<sup>17</sup> have pointed out, much of the treatment procedure stems from the relations between individuals and groups within the institution, and the staff's behavior becomes crucial.

Our former methods of teaching nursing personnel are believed actually to perpetuate social distance between staff and patients, rather than facilitate communication and check distortions. Formal teaching of limited psychiatric material often fosters defensiveness on the part of the staff member and when his need to be "junior psychiatrist" is met rehabilitation of the patient is hindered. The concept of "social therapy" as distinct from "psychotherapy" has important implications. The primary role of the social therapist is one of providing opportunity for the patient to relate to others and to encourage him to feed back his feelings to the community in order that they may understand him and help him. In this way the treatment process is hastened, as he now receives help from all members, consistently and for 24 hours per day. Dangers and pressures of individual psychologic interpretation are lessened, and social relations are fostered.<sup>18</sup>

As all staff members and patients learn to feed back information to the whole community it is possible to arrive at therapeutic goals for each patient—the decisions become community ones and everyone understands the goals and shares in the treatment process. The success of treatment in the relatively short time of hospitalization (e.g., four to six months at the Social Rehabilitation Unit and at the Cassel) for chronic character and behavior disorders and neurotic difficulties is thus understandable as each patient has in a sense many therapists and he too becomes a therapist. More important he is living in a milieu which is consistently therapeutic and treatment as Maxwell Jones expressed it is like being put in a "pressure cooker" to get the patient "well done" in a hurry.

# OPERATIVE RESULTS IN LUMBAR 'DISK' SYNDROME

Majority of Patients Return to Full Duty

GAIL G. CLARK *Commander MC USA*

**T**HE EFFECTIVENESS of modern operative therapy of herniated lumbar nucleus pulposus was revealed by review of the cases of 100 unselected consecutive patients who were operated on in this hospital during 1952 to 1955. All of these patients were military personnel on active duty, 77 in the United States Army, 1 in the British Army, and 22 in the United States Marine Corps. All had the same general management post-operatively.

## METHOD OF TREATMENT

Conservative management was tried in all cases for a period of from two to six weeks. This consisted of bed rest on a very firm mattress and analgesics as necessary. Tolserol (brand of meprobamate) was administered when muscle spasm could be identified by palpation or observation of the back in motion, or if roentgenographic studies indicated that the normal lordotic curve was straightened. If the patient showed improvement on this regimen, he was sent to physiotherapy for exercises to regain maximum power in his back and gluteal muscles.

Myelography was performed if there were signs of a single radicular syndrome or if incapacity for work persisted in spite of conservative therapy. It was never done for symptoms alone except in the very rare case where, in spite of absence of radicular signs, the patient insisted that he could not perform his usual duties. In two of five such cases, a myelographic defect consistent with herniation of a nucleus pulposus was observed, and these two patients were operated on.

Myelography was performed preoperatively in all but one of the 100 cases. The reasons for this were twofold. (1) Even though a single radiculitis had been identified by clinical tests and the affected dermatome labeled, there was always the possibility that

a pre or post fixed spinal cord had caused the clinical labeling to be in error by one vertebral level (2) more complete and thorough records were made available for preoperative study to identify the size and extent of the mass pushing on the nerve root

The operative procedure was the popular technic of interlaminar exploration in most cases without removal of bone. Occasionally edges of the lamina above and below the lesion were rongueured away for more adequate exposure. A hemilaminectomy was performed in one case only, this patient had had extrusion and scattered fragmentation of his nucleus pulposus. All operations were performed under general anesthesia.

Postoperative management was considered to be one of the most important elements in the patients treatment. After being operated on in the morning most patients were allowed to get out of bed that same night and attempt to void into a urinal while standing, by the edge of the bed. Every patient was out of bed once on the first postoperative day. All were urged to sit on the side of the bed frequently to dangle their legs and were allowed out of bed for short intervals for the first five postoperative days. Walking was allowed as the patient desired but always for very short periods. Stitches were removed on the seventh postoperative day. After this the patient was transferred to the convalescent ward where he was allowed to take frequent but very short walks and was instructed in exercises designed to achieve the maximum power in the lumbar and gluteal muscles.

Two weeks postoperatively the patient was given 30 days sick leave with strict orders to continue his exercises at home for five minutes of every waking hour. All patients reported by mail after two weeks of their four weeks leave, that they were pursuing this regimen at home. On return from sick leave physiotherapy was increased for a period of 10 days after which the patient was re evaluated.

## RESULTS

The results obtained by the management described may be summarized as follows:

### *Returned to duty (75 per cent)*

The military record will appraise the variety of traumatic duties that were accomplished successfully by carrying the rank and rate of the 37 patients who returned directly to full duty 2 months after operation and of the 18 additional patients who eventually returned to full duty. They were as follows: Air Controller 5, Aviation Mechanic 1, Marine Aviator 1, Electrician 1, Aviation Structural Mechanic 1, Airman Aviator 1, Electrician 1, Technician 1, Boatwain 1, Mate 1, Boilermaker 1, Builder 1, Damage Controller 1, Electrician 1, Marine 2, Engineer 2, Electrician 1, Technician 1, Fireman 1, Photographer 1, Gunner 1, Marine 1, Chief Gunner 1, Hospital Corpsman 1, Inter-Communicator 1, Electrician 1, Machinist 1, Marine 1, Quartermaster 1, Radioman 1, Seaman Apprentice 1, Steward 1, Ship Serviceman 2, Stenographer 1, Seaman 1, Torpedoman 1, Mate 1, Yeoman (WAVE) 1, Marine 1, Private 1, First Class 1, Marine 1, and 14 Navy officers.

57 patients returned to full duty 2 months after operation

16 returned to full duty after 3 to 6 months of limited duty

1 was sent to the Physical Evaluation Board and then returned to full duty

1 was sent to limited duty then to the Physical Evaluation Board and finally returned to full duty

#### *Discharged (25 per cent)*

14 patients were not returned to military duty and were discharged from the military service 3 to 4 months postoperatively

9 were sent to limited duty but after 6 months were not improved enough to return to full duty and were discharged

2 were sent to full duty but were unable to perform their work adequately and were discharged

Of the 14 patients in the group listed above as "not returned to military duty," 8 were sent to the Physical Evaluation Board at their own request, because they desired evaluation at the end of enlistment, prior to discharge from military service. It is believed that some of those men could eventually have been returned to full duty if expiration of enlistment had not prevented their being sent to limited duty for a period and then re-evaluated.

Those patients who were discharged from military service because of disability were estimated by the Physical Evaluation Board, on the basis of symptoms as well as signs alone, to have an average of 30 per cent disability at time of discharge. Of the 25 persons discharged, 1 was rated at 0 per cent disability, 1 at 10 per cent, 10 at 20 per cent, 4 at 30 per cent, 3 at 40 per cent, 5 at 50 per cent, and 1 at 60 per cent.

#### DISCUSSION

The urgency of reporting these cases was brought to my attention when two Chief Hospital Corpsmen were selected for Warrant Officer and there was hesitancy in qualifying them physically for their commission, solely because they had a history of interlaminar explorations for herniation of a lumbar nucleus pulposus. *One had been on full duty for 7 years and another for 5 years.* It is significant that three quarters of the patients herein reported returned to duty, and that in many cases this involved vigorous activity. Two pilots returned to flying planes, and boatswain's mates and motor mechanics returned to their regular work.

The follow up period on these patients ranged from 6 to 28 months. A longer period would be of interest in evaluating long term results, and probably would disclose a few men who were unable to remain on full duty, however, there is a definite need, now, to dispel common and unjustified pessimism toward the results of treatment in this disease. In this group the patients operated on returned to full and

# ORAL LICHEN PLANUS AND LEUKOPLAKIA

## Differential Diagnosis and Treatment

HARRY L. LEVIN *Captain DC USNR*

**A** DEFINITIVE diagnosis of a disease with manifestations in the oral cavity frequently requires a variety of laboratory criteria. Lichen planus (figs 1 and 2) and leukoplakia (figs 3 through 5) are two such diseases. Because the latter is considered to be precancerous it is the responsibility of the dental and oral surgeon to be able to differentiate it from the former.

Lichen planus of the mouth is not an important disease per se as it causes no subjective symptoms and has no serious sequelae. It is of great significance however from a diagnostic standpoint as it is frequently mistaken for leukoplakia, a disease of great importance. It should be emphasized that patches of leukoplakia that have reached the verrucose papillomatous and ulcerated stage or contain hard nodules may be cancerous (squamous cell carcinoma grade one half) and therefore require an adequate biopsy.

In typical cases lichen planus and leukoplakia each present a definite histologic picture,<sup>1</sup> however in clinically atypical cases a corresponding nonspecific histologic picture is frequently observed and a clear cut diagnosis is not always possible. Additional biopsy specimens taken at intervals usually aid in establishing a correct histologic diagnosis.

Lichen planus is characterized by lily-of-the-valley-like or annular markings on the buccal mucosa with definitely outlined round or polygonal pearly white nodules, whitish streaks on the tongue and accompanying lesions on the skin.<sup>2</sup> A biopsy may show a network of bluish white lines known as Wickham's striae. Early lesions usually are erythematous with a violaceous tinge while older ones tend to be darker.<sup>3</sup>

Brocq gave an accurate diagnostic histologic picture of lichen planus and cited a case in which the lesions of this disease and those characteristic of leukoplakia appeared in the mouth at the same time. Darling and Crabo<sup>4</sup> emphasized the oral manifestations of these two diseases; however the mouth lesions associated

*Figure 1 Lichen planus of the buccal mucosa, right side in a male patient of nervous temperament*

with lichen planus are only part of a generalized disease process and are, in effect, skin lesions modified by environment. Nevertheless, the basic pathology and clinical appearance of the skin lesions are relevant to an understanding of the disease in the mouth. Lieberthal<sup>7</sup> described the papules observed in lichen planus, and which may become verrucose. Fox<sup>8</sup> emphasized the importance of differentiating moniliasis from lichen planus as their clinical appearance may simulate one another. With the introduction of the antibiotics, moniliasis of the mouth has become more common than lichen planus. Furthermore, Fox's claims are not in accord with other investigators. Cawley and Kerr<sup>9</sup> and Ormsby and Montgomery<sup>10</sup> described the initial lesions of lichen planus as being bright red in color and later assuming a reddish purple or violaceous hue. With clearing of the eruptions, hyperpigmented macules commonly persist at the site for weeks or months. Cooke<sup>11</sup> described an atrophic form of lichen planus of the mouth, frequently associated with erythematous areas and shallow ulcerations.

The differentiation of lichen planus and leukoplakia of the oral cavity is summarized in table 1.

*Figure 2 Lichen planus of the buccal mucosa left side of a male patient who is a moderate smoker*

*Figure 3 Leukoplakia of the buccal mucosa of a male patient who is a heavy smoker. Note verrucose characteristics of the lesion. (Courtesy of Dr A Budner Lewis and the Rhode Island Hospital)*

Figure 4 Leukoplakia of the buccal mucosa in the mouth of a heavy smoker showing rather extensive advanced plaques with ulcerations indicative of early malignancy (Courtesy of Dr A Budner Lewis and Rhode Island Hospital)

Figure 5 Leukoplakia with ulceration of the oral mucosa in the mouth of a heavy smoker. The lesion may no longer be considered leukoplakia as the lesion is well advanced into the malignant stage (squamous cell carcinoma) (Courtesy of Dr A Budner Lewis and Rhode Island Hospital)

TABLE 1 *Differentiation of lichen planus and leukoplakia of the oral cavity*

	Lichen planus	Leukoplakia <sup>12</sup>
1 Contributory factors	Often associated with nervous tension or instability	Found at sites of irritation (sharp ragged edges of teeth ill fitting dentures et cetera) or of previous irritation such as the site of a former syphilitic gumma Usually associated with poor dental hygiene and excessive smoking
2 Site of lesions	Found as frequently in men as in women  Found on buccal mucosa alveolar ridges dorsum of the tongue and palate May or may not be accompanied by cutaneous lesions Skin lesions when present are most numerous on flexural aspects of forearms and wrists and inner surfaces of thighs and knees There may be alopecia if scalp lesions are present	More common in men than in women  Most common site in the oral cavity May be found on the mucous membrane of the other parts of the body chiefly the vulva
3 Gross morphology	The basic lesion is the violaceous filiform network and meshes of lacework formations on the buccal mucosa appearing as small flat topped angular papules	Usually present as a leathery thickening of the mucosa with a pearly silvery sheen Occurs as lactescent superficial patches of various sizes and shapes which may coalesce to form rather extensive sheets
4 Extension	No adenopathy is present	Lymph nodes usually are not involved until the malignant stage is reached

TABLE 1 *Differentiation of lichen planus and leukoplakia of the oral cavity—Continued*

	Lichen planus	Leukoplakia <sup>12</sup>
5 Histopathology	<p>Hyperkeratosis increased thickness of the granular layer which is usually missing in the normal mucous membrane. The cells in the granular layer are coarse and well formed. Several rows of these cells are present. Acanthosis is also present with destruction of the basal layer by the infiltrate from the upper dermis. Lymphocytes are plentiful and invade the stratum Malpighii.</p> <p>The rete ridges on occasion show the "saw tooth papillae which is characteristic" (figs 9-11)</p>	<p>Epithelial horny pearls or cell nests are common. Hyperkeratosis of the superficial layer of the stratum corium with rete ridges in the Malpighian cells undergoing abnormal, premature, or imperfect keratinization resulting in a dyskeratosis (figs 6-8).</p> <p>Neither the hyperkeratosis nor the lymphocytic infiltration is as localized as in lichen planus.</p>
6 Symptoms	<p>May be painful at the onset in the oral cavity. Upon the skin surfaces it becomes very "itchy" and annoying.</p>	<p>Usually not painful until the advanced stages.</p>
7 Terminal picture	<p>After the disease becomes chronic the infiltrate decreases. The plaque like formations develop verrucose tendencies or may disappear spontaneously. Recurrence is common.</p>	<p>Acute leukoplakia may develop rapidly become thickened, actually ulcerate, become papillomatous with verrucose appearance and is more apt to become malignant than the chronic type. Traumatic calluses clear up when source of irritation is removed.</p> <p>One out of every fourth case will develop malignant tendencies—squamous cell carcinoma.</p>

*Figure 6. Leukoplakia. The surface epithelium of oral mucosa showing marked hyperkeratosis. The rete ridges appear somewhat irregular although acanthosis is not excessive. The granular layer is prominent. The basal epithelial cells exhibit hyperchromatism. ( $\times 91$ ) (Courtesy of the Armed Forces Institute of Pathology)*

*Figure 7. Leukoplakia. The surface epithelium shows hyperkeratosis and parakeratosis and irregular acanthosis. Dyskeratosis is evident by the loss of normal maturation of the epithelial cells changes in the size and shapes of the cells and loss of polarity. The basal layer is unbroken and there is no evidence of invasion. The dermis contains a lymphocytic infiltration. ( $\times 146$ ) (Courtesy of the Armed Forces Institute of Pathology)*

Figure 8 Leukoplakia. Moderate dyskeratosis is evident here as characterized by the hyperchromatism and variations in the cell size and shape ( $\times 186$ ) (Courtesy of the Armed Forces Institute of Pathology)

Figure 9 The epithelium in this strip of oral mucosa shows acanthosis with irregular lengthening of the rete ridges. The upper part of the submucosa contains a sharply localized inflammatory cell infiltrate which is in close relation to the basal cell layer. This is consistent with lichen planus ( $\times 58$ ) (Courtesy of the Armed Forces Institute of Pathology)

Figure 10 Parakeratosis shown in greater detail with an orderly maturation of the oral epithelium. There is marked infiltration of plasma and lymphocytes in the upper dermis a condition found in lichen planus. (Courtesy of the Armed Forces Institute of Pathology)

Figure 11 Lichen planus. Characteristic infiltration of plasma cells and lymphocytes in the region of the basal epithelial layer ( $\times 213$ ) (Courtesy of the Armed Forces Institute of Pathology)

## TREATMENT

Treatment of lichen planus is usually unsatisfactory. In former years benefit was claimed in some cases from the administration of arsenic and mercury. Radiation therapy provides no appreciable relief. Radium and ultraviolet rays are equally ineffectual. Cessation of smoking and moderation in the use of condiments are helpful. Gentian violet (methylenedianiline chloride) (1 per cent) is used widely, a 1:1,000 solution of Zephiran Chloride (brand of benzalkonium chloride) and tincture of Merthiolate (brand of thimerosal) have been tried without success. Recently I have used a topical ointment of fludrocortisone acetate (0.25 per cent)\* for treatment of extensions of the dermatologic conditions into the oral cavity, with gratifying results. This material is one of the most potent of the adrenal cortical hormonal agents produced, and it is absorbed readily by the mucous membrane and skin. The use of this ointment in the treatment of other recalcitrant diseases of the oral cavity is definitely indicated. Others<sup>11-13</sup> also reported favorable results in the oral lesions with the topical application of hydrocortisone ointment (2.5 per cent).

Ward<sup>1</sup> called attention to the possible role of vitamins A and C in the cause of leukoplakia. In support of this theory it has been noted that patients treated with large daily doses of vitamin A and C (100,000 units of vitamin A and 500 mg of vitamin C) there is a marked improvement in leukoplakia after a period of from 1 to 3 months. Electrodesiccation and fulguration are usually effective in the early lesions of leukoplakia.

Miller<sup>14</sup> stated that "precancerous lesions are best eradicated by surgery rather than by x-ray or radium since sufficient doses to destroy the lesion will also cause radiodermatitis, which in itself is subject to epitheliomatous degeneration at some later date."

Certain dermatologic diseases have oral manifestations which resist all forms of treatment within the scope of the dental surgeon. Under these conditions the dental surgeon should refer the patient to a capable internist or dermatologist for confirmation of diagnosis and treatment.

## SUMMARY

Lichen planus and leukoplakia present clinical and histologic pictures which require careful diagnostic procedures in establishing a mutually distinctive diagnosis. Treatment of either disease with topical fludrocortisone acetate ointment (0.25 per cent) has produced gratifying results.

\*Fluorone Acetate a brand of fludrocortisone acetate was supplied through the courtesy of Merck Sharp & Dohme Division of Merck & Co. Inc. Philadelphia Pa.

**ACKNOWLEDGMENTS** I wish to thank Dr. Walter F. Lever, Massachusetts General Hospital, and Dr. Lyon P. Strean, Merck Sharp & Dohme Division of Merck & Co., Inc. I also wish to thank Col. Joseph L. Bernier, Armed Forces Institute of Pathology, for his fine photomicrographs.

# CUTTING CHARACTERISTICS OF DENTAL BURS

As Shown by High Speed Photomicrography

JACK L. HARTLEY Major USAF (DC)  
DONALD C. HUDSON Colonel USAF (DC)  
WILLIAM T. STEFFEN A. B.  
WARREN P. RICHARDSON

**L**ITTLE is known of the cutting action involved in the use of the dental bur for cavity preparation in a human tooth. A better understanding of this mechanism could logically lead to improvement in the design and use of dental rotating cutting instruments. Although considerable information is available on the cutting mechanism of industrial abrasive wheels and milling cutters, this information is not directly applicable to dental instruments because the properties of human tooth enamel and dentin differ greatly from those of other materials. Also, the dental instruments are much smaller than the usual industrial grinding wheels and cutters. The patient's sensitivity to frictional heat, to vibration, and to pain caused by cutting add direct and unique factors to the design of dental burs.

It was believed that certain basic information on the manner of performance of dental burs would be revealed through high speed photography of these instruments as they rotate under load in contact with the test materials human enamel and dentin. The program of high speed photography was, therefore, initiated as part of a continuing study of rotating dental burs.

## EXPERIMENTAL PROCEDURE AND RESULTS

A bur evaluating machine with accessory timing and controlling features, which had been constructed at the United States Air Force School of Aviation Medicine, Randolph Field, Tex., and

---

This report concerns part of the dental research program conducted at the National Bureau of Standards in co-operation with the Council on Dental Research of the American Dental Association, the Army and Navy Dental Corps, the Air Force Dental Service, and the Veterans Administration. Mr. Sweeney is Chief of the Dental Research Section in which Colonel Hudson and Major Hartley were Guest Workers. Mr. Richardson is Chief of the Photographic Services Section.

Col. Hudson and Maj. Hartley are now assigned to the School of Aviation Medicine, Randolph Air Force Base, Tex.

shipped to the National Bureau of Standards was modified to permit placement of cameras above the specimen. In preliminary investigations high speed still photographs were made employing a flash unit which emitted an intense light two millionths of a second in duration. This light effectively stopped the action of a dental bur in rotation. The light was focused by means of a condensing lens system which increased the illumination by concentrating the light on the bur head. Four by five inch film rated at a speed of ASA 64 Tungsten (American Standards Association exposure index) was exposed by the open flash method in a standard laboratory camera. The lens opening was  $f/5$ . Magnification was approximately 10 diameters.

A number 559 tungsten carbide bur was photographed cutting a glass microscope slide. The load was 300 grams and the speed of rotation was 5 000 revolutions per minute (r p m) (fig 1). Interpretation of the photograph indicated that a pulverizing action rather than a true chip formation had taken place. The powdered glass debris accumulated on the entrant side of the excavation. This phenomenon is a possible explanation for clogging of the bur in that the debris was not thrown out at the exit side but was carried around to the entrant side of the excavation where it was occasionally picked up and carried back through the cut. Heat dissipation was hindered by the accumulation of debris at this point which may be an explanation for chipping which occurs at the entrant side.

Another number 559 tungsten carbide bur rotating at 5 000 r p m cutting a cast resin under a 200 gram load was photographed by the same method. This material was used in previous work as a substitute for dentin. True chip formation can be seen in the photograph (fig 2). This should be expected when a milling type cutter is employed in its proper medium. The chips are accumulated on the exit side of the excavation probably because they are too large to be carried around by the vortex of air created by the revolving bur.

These still photographs were of some value and served to stimulate interest in observing the instruments photographically under dynamic conditions. The single exposure high speed flash method of photographing a rotating dental bur did not permit sequential studies of the cutting action on any particular blade.

A 16 mm high speed motion picture camera which operated at a speed of 3 000 frames per second (f p s) was first used in obtaining slow motion studies of dental burs. Adequate magnification of the small dental burs required the use of an  $f/40$  six inch telephoto lens with a two diopter supplementary lens and an extension tube eight inches in length. The camera was mounted on a heavy tripod directly over the precision chuck of the bur evaluating machine. Exposure, at the rate of 3 000 f p s was

Figure 1 A 2 microsecond flash photograph. Direction of rotation is counter clockwise as viewed by the reader. Carbide bur cutting glass. 5 000 r p m. 300 gram load. (Bur diameter approximately 0.05 in.)

Figure 2 A 2 microsecond flash photograph. Direction of rotation is counter clockwise as viewed by the reader. Carbide bur cutting a dentin substitute (Bakelite cast resin) 5 000 r p m. 200 gram load. (Bur diameter approximately 0.05 in.)

1/15,000th of a second per frame. This extremely short exposure, combined with the reduction in effective aperture of the lens due to the extension tubes,\* required a high intensity light source. Eleven 750 watt focusing photoflood bulbs were arranged in a circle above the subject. An internally chrome plated ring placed around the chuck aided in concentrating light on the bur head.

Reversal type 16 mm motion picture film rated at ASA 64 Tungsten was used when motion pictures were made for projection. Negative film with the same characteristics was employed when single frame enlargements were required. A 100 foot roll of film required but 1.25 seconds for exposure at 3,000 f.p.s. The action recorded on the film in this period was extended to approximately three minutes by projection at the normal speed of 24 f.p.s. With the addition to the equipment of two other cameras capable of speeds of 7,000 and 14,000 f.p.s. the three cameras effectively slowed the action of burs rotating at 2,500, 5,000 and 10,000 r.p.m. respectively. These speeds correspond approximately to low, average, and high rotational speeds for operating dental hand pieces.

Additional illumination was required for the faster cameras since the exposure was only 1/35,000th of a second for the 7,000 f.p.s. camera and 1/70,000th of a second for the 14,000 f.p.s. camera. Four 1,000 watt spotlights that contained parabolic reflectors were used. Their light was further concentrated by means of 2x condensing lenses four inches in diameter (fig. 3). A foot candle meter reading indicated over 300,000 foot candles of light was available in an area of two square inches around the specimen. The short interval of time involved in turning on the lights energizing the camera and turning off the lights minimized damage to the specimen or equipment from heat.

The most effective studies of the burs rotating in slow motion were accomplished by observing the projected motion pictures.\*\* Some information can be obtained from prints enlarged from individual frames of the motion picture film although such prints do not show details clearly (fig. 4). A complete rotation cycle of a bur turning at 2,500 r.p.m. and photographed at 3,000 f.p.s. could be observed in approximately 74 frames. Every fourth frame from a typical rotation cycle was enlarged and printed. Six key pictures were chosen from such a print series for figure 4.

---

The formula  $EA = \frac{V}{F}$  applies. Where EA = effective aperture, V = lens film distance, f = marked lens aperture and F = focal length in inches.

A 16-mm sound film running approximately 15 minutes and showing some of the burs studied in this work may be obtained on loan by writing the Office of Technical Information, National Bureau of Standards, Washington 25, D. C.

Figure 3 High-speed motion-picture camera and auxiliary equipment for slow-motion photography of rotating dental burs. Below the camera is the bur-evaluating machine the camera control unit is at lower left

The top row of pictures in figure 4 shows the sequence of events from left to right as a number 559 eight bladed tungsten carbide bur cuts human enamel at 2,500 rpm with a 300 gram load. This bur was 0.003 of an inch eccentric as measured by total runout. It can be seen that only four blades were actually cutting, and that in one phase of its rotation the bur was not in contact with the tooth structure. Some of the debris, finely powdered, followed the vortex of air about the bur and was carried back into the excavation. The bulk of the cut material was deposited at the exit side, where it is seen to have accumulated. Very little cutting was evident. The debris created by the steel

THE INSTRUMENTS ABOVE WERE ROTATING AT A SPEED OF 2 500 RPM AT A LOAD OF 300 GRAMS

*Figure 4 High-speed motion-picture 16-mm frames enlarged to show stages in the rotation cycle of typical dental bur (Bur diameter approximately 0.05 in.)*

bur while cutting enamel was so finely powdered that it was barely visible

A number 559 six bladed steel bur cutting human dentin was photographed at 3 000 f p s The load was 300 grams speed 2 500 r p m The key pictures from a cycle of rotation (fig 4 middle row) show definite chip formation although the chips are fragmented and tend to follow the instrument as it rotates Bounce due to eccentricity is not visible however a study of the debris reveals that the cutting was intermittent The bottom row of pictures in figure 4 illustrates the cutting cycle of a number 559 tungsten carbide bur in dentin The chip formation is superior to that seen in the case of a steel bur cutting the same material

The first photograph in the series shows the bur in a phase of its cycle of rotation, in which a great amount of dentin has been removed and is leaving the excavation. The blades in cutting position at this stage are ineffective since the instrument is 0.003 of an inch out of round, or eccentric. The fourth photograph in this series shows the bur after rotation of 150 degrees, it can be seen that the blades now in the excavation are cutting effectively. This intermittent cutting action was observed in all eccentric burs studied. Increasing the load to 500 grams accentuated the intermittent action.

In the slow motion pictures obtained in this investigation chip formation is revealed in detail as the individual bur blades pass through the excavation. The manner of operation of various types of bur blade designs can be readily studied as the bur appears to rotate slowly. For example, a chip that is formed by one type of bur blade may be seen to break away from the parent substance, strike the blade ahead, and cause chipping. Fine comminuted chips created by a bur that is rotating at too low a speed (2,500 r.p.m. in this case) and thus cutting ineffectively, are seen to follow the vortex of air about the revolving bur. At 5,000 r.p.m. this condition was not improved. At 10,000 r.p.m. a definite improvement in clearance of debris is noted. The effect of improper design is readily seen in some carbide burs, which are observed to cut very poorly even though they do not dull.

It is believed that the superior workmanship of carbide burs in general, noted on comparative microscopic examination of steel and carbide instruments, is a factor affecting the cutting ability of the two types. Curled edges, seen on the steel bur (fig. 5) rapidly dull and break. Rounded edges of the cross cut areas

Figure 5 New unused steel bur. Note the curled and drawn edges. (Bur diameter approximately 0.05 in.)

created during the machining of the bur may cause clogging. These conditions were not seen on the carbide burs examined (fig 6). The extreme hardness of tungsten carbide permits burs of this material to cut hard substances with less dulling of the

*Figure 6. New unused carbide bur. Note the clean-cut edges and lack of dulling surfaces. (Bur diameter approximately 0.05 in.)*

blade edges which present a clean, well machined appearance. However, neither steel nor carbide burs which are designed as milling type cutters, appear to operate efficiently in a material as hard as human enamel. No true chips are seen to form as these instruments cut tooth enamel. Photomicrographs of typical samples of debris from enamel and dentin produced by steel and carbide burs are shown in figure 7. The great difference between enamel and dentin chips is evident. However, no consistent difference is seen between the chips produced by steel and those produced by carbide instruments. Chips produced in dentin by carbide bur brand X are somewhat larger than those from carbide bur brand Y.

### CONCLUSIONS

High speed motion picture photography of dental burs under actual cutting conditions permits detailed slow motion study of the action of each bur blade throughout the cycle of rotation.

In enamel, neither steel nor carbide instruments produced true chips, as would be expected from a milling type cutter. Both steel and carbide burs produced true chip formation and were more efficient in dentin than in enamel.

These photographic studies, when combined with the conventional laboratory testing methods, provide a new and more complete approach to the study and design improvement of rotating dental cutting instruments.

#### SUMMARY

High speed still and motion picture photomicrography has been used in the study of the mechanism of cutting of dental burs. Two microsecond flash still photographs were made of dental burs cutting glass and cast resin at 5,000 r p m with a load of 300 grams. Slow motion studies employing high speed motion

picture cameras at 3 000 7 000 and 14 000 f p s were made of steel and carbide burs running at 2 500 5 000 and 10 000 r p m with a load of 300 to 500 grams the materials cut were human enamel dentin and test substitutes for tooth structure The action occurring within a second was extended to approximately three minutes for study by projection at 24 f p s These methods permitted observations of clogging intermittent cutting and eccentric rotation

#### NATURE TAKES ITS COURSE

Everyone survives all illnesses except his last often uninfluenced by medical care not infrequently hindered by medical care sometimes decisively helped by it That is the cold unpalatable truth Fortunately lay people have little appreciation of this and I cannot say that we make any great effort to enlighten them This element of deception may be in the patient's best interests and is not inherently unscientific or immoral but scientific apostasy sets in when we ourselves fail to recognize when we have only played a passive role It is often hard for us to realize that the peptic ulcer has healed spontaneously without aid from our dietetic regime of food and sago We readily ignore the fact that the good season the hay-fever patient has enjoyed after our course of pollen inoculations is due to the weather We readily believe that our series of recoveries from myocardial infarction is due partly at least to our regime of strict bed rest

# SURGICAL TREATMENT OF PLANTAR CORNS

BEN A. RUTLEDGE *Lieutenant Colonel MC USA*

ALVIN L. GRIFFIN *Specialist third class USA*

**C**ORNS occurring inferior to the metatarsal heads are often a major disability, especially for persons whose occupations demand long hours of weight bearing. Although these growths occasionally are asymptomatic, symptoms usually vary from slight discomfort to inability to bear weight. The incidence is fairly high, and intractable corns frequently receive only minimal and ineffective treatment.

A plantar corn (clavus) tends to lie directly beneath a weight-bearing bony prominence. It is often mistaken for a plantar wart (verruca). When in doubt as to the correct diagnosis, removal of the superficial layers will disclose the true nature of the lesion. A wart is characterized by elongated dermal papillae with enlarged blood vessels, is sharply demarcated by a wall of fibrous tissue, and is tender even on side-to-side pressure. A corn presents a horny, conical core of closely packed epidermal cells arranged in concentric layers, and is primarily painful only on direct pressure. Climatic changes seem to intensify the pain. A possible explanation for this is that the keratinized material contained in a corn, which is hygroscopic, tends to become swollen when the air is moist.

## TYPES OF TREATMENT

The literature contains a multitude of reports concerning treatment of plantar warts, whereas only a few reports concern treatment of plantar corns. Many authors erroneously use the term plantar wart in reference to any plantar excrecence, and we believe that the "plantar warts" referred to in many articles are in actuality corns.

The surgical treatments reported vary from simple removal of the corn to more radical procedures such as local excision requiring skin grafting, and plastic operations as described by Ghormley and Lipscomb,<sup>1</sup> Haggart,<sup>2</sup> and Blair, Brown, and Byars.<sup>3</sup> Condylectomy, to remove the cause of a plantar corn by removing the underlying bony prominence, was described by DuVries.<sup>4</sup> A more radical procedure reported by Dickson<sup>5</sup> consists of "removal

of a V shaped section of the foot including a wide excision of the wart with the corresponding toe and metatarsal " key" advocated removal of the metatarsal head

There is no question that treatment of an intractable plantar corn should be directed toward removal of the cause : e the underlying bony prominence

This article reports a method of surgical treatment for such corns occurring beneath the 2d 3d or 4th metatarsal heads of the foot No originality is claimed We believe that removal of the metatarsal head and at least one third of the shaft is an adequate procedure for treatment of intractable corns in these areas Figure 1 illustrates the amount of bone removed Thirty plantar corns have been treated by this method The immediate postoperative period for all patients has been excellent however our longest follow up is 18 months

Figure 1 Roentgenogram showing amount of bone removed.

## OPERATIVE PROCEDURE

A short dorsal longitudinal incision is made over the offending metatarsal head. The extensor tendons are retracted, the periosteum reflected, and the metatarsal is cut with a bone cutter through the junction of the middle and distal one third of the shaft. The metatarsal head and distal shaft are excised by sharp dissection, and the roughened portion of the distal end of the shaft is rounded and rasped. No postoperative treatment is given, other than bed rest and elevation of the foot for three to four days.

Most of our patients were able to walk by the fifth day and were relieved of pain from the corn immediately. Service personnel returned to duty in three weeks, on the average. The corns disappeared about the eighth postoperative week. As a group, these patients were notably grateful for the immediate relief obtained.

This procedure leaves no scar on the weight bearing surface of the foot. The toe recedes one eighth to one fourth of an inch (cosmetically this is hardly noticeable), and the toe still functions. Formation of new corns on adjacent metatarsal heads thus far has not been observed. A five year follow up is planned.

## SUMMARY

Plantar corns that are intractable to conservative management should be treated by removing the underlying bony prominence. Good results have been observed in 30 cases in which the offending metatarsal head and about one third of the shaft were removed according to a simple technique that is described.

## Clinicopathologic Conference

3415th U S Air Force Hospital Lowry Air Force Base Denver Colo

### CENTRAL NERVOUS SYSTEM BLEEDING AND SPLENOMEGALY

**Summary of Clinical History** A 35 year-old white man was admitted to the hospital on 9 April 1956. He was unable to give a good history and most of the history was therefore obtained from his friends and relatives. For about two weeks prior to admission to the hospital the patient had had a staggering gait, vertigo, and troubles of intellect. On the morning of admission he had great difficulty in walking with a tendency to fall to the left. The same day he also became nauseated and vomited. According to his mother and sister the patient had had abdominal pains for the last three or four years. His appetite had been extremely poor for about one year and he had eaten mainly canned food.

**Military history** revealed that the patient had spent about one year in Korea, returning to the United States two years ago. He spent four years in Germany (from 1948 to 1952). He was an instructor in weapons. He never indulged in alcohol.

**Physical Examination** On admission the patient appeared normally developed but chronically ill. The blood pressure was 120/70 mm Hg, pulse rate 100 per minute, respirations 20 per minute, temperature 98°F. On examination of the eyes, nystagmus was noted on lateral gaze. Pupils, fundi, and vision fields were normal. Ears, nose, and throat were negative and there was no nuchal rigidity. The heart and lungs were normal. Examination of the abdomen revealed a palpable spleen 4 cm beneath the left

---

Col. Lev M. Bruns, USAF (MC), Commanding Officer, Fomth Medical Ad Lbrary Serv c. Capt. Charles R. Frick, USAF (MC), Chief Medical Serv c. Capt. Bernard C. R. Bulky, USAF (MC), Chief Laboratory Serv c.

costal margin. It was smooth, firm, and nontender. The liver was not palpable, and there was no abdominal tenderness. Gonitain and rectum were normal. Examination of the skin revealed sparse hair distribution. One spider angioma was noted on the back of the neck. There was no icterus. No lymph nodes could be palpated. Examination of the extremities revealed clubbing of the fingers, and there was slight pitting edema of the legs. Brownish discoloration was noted on the lower parts of both legs. Neurologic examination revealed slurring of speech and marked incoordination. Romberg sign was positive with the eyes open, and the patient had a tendency to fall to the left. The gait was extremely unsteady, also with a tendency to fall to the left. There was no muscular weakness. All the reflexes were hyperactive but equal. No pathologic reflexes could be obtained.

**Laboratory Studies.** Serologic examination was negative. Roentgenograms of the chest and skull were reported normal. A flat abdominal roentgenogram revealed an enlarged spleen. Blood tests showed a white blood cell count of 4,500/ $\mu$ l with a differential of 60 per cent neutrophils and 40 per cent lymphocytes. Hemoglobin was 9 g/100 ml, red blood cells, 2,810,000/ $\mu$ l, hematocrit, 32 ml/100 ml, corrected sedimentation rate (Wintrobe), 22 mm, platelet count, 37,200. The red blood cells were reported as macrocytic. Coombs' test was negative. Bone marrow aspiration showed erythroid hyperplasia, with a myeloid erythroid ratio of 1:1.5. No megakaryocytes were seen. A spinal tap was performed, the fluid was xanthochromic, otherwise not abnormal. Liver function tests showed a cephalin cholesterol flocculation of 4+, thymol turbidity of 7.1, total proteins, 5.4 g/100 ml (2.5 g/100 ml albumin, and 2.9 g/100 ml globulin) (A/G ratio 0.86). The total bilirubin was 0.9 mg/100 ml, with a direct bilirubin of 0.35 mg/100 ml. Prothrombin time was 75 per cent of normal. Blood urea nitrogen was 15 mg/100 ml. A routine urinalysis was negative. The amount of urobilinogen in the urine was normal, the urine was negative for bilirubin. The urine turned black on standing, and examination for porphyrins by the Watson test was positive.

**Course in Hospital.** The patient was placed on bed rest and treated for nausea and vomiting. His course was downhill. Headache, slurring of speech, and increased irrational behavior were present. On 13 April the patient became comatose. At this time all his extremities were flaccid. Reflexes remained hyperactive, with a sustained ankle clonus and a positive Babinski bilaterally. Severe nuchal rigidity was present. A repeat spinal tap was again xanthochromic. The patient was given blood transfusions, Metacorten (brand of prednisone), and Terramycin (brand of oxytetracycline hydrochloride). His condition continued to deteriorate, and he began to have convulsive episodes with spasm of the

glottis and difficulty with respiration. An airway was put in place and he was placed in an oxygen tent. The patient died on 14 April 1956 at 1455 hours.

### DISCUSSION

Doctor Schneck \*I think we can begin by first looking at the only x ray of any significance this simply shows an enlarged spleen which was palpable in the initial physical examination and through the hospital course. This man was 35 years old which is significant because that is fairly young to have a fatal illness of the character that his apparently was. He came in on 9 April and was unable to give a good history. There could be several reasons for this inability to speak coma thickness of speech confusion or many others. I saw this man one night two days before he died and from my observation would presume that confusion was the main reason for his not being able to give a good history. Most of the history was obtained from friends and relatives who observed staggering gait vertigo and troubles of intellect in the patient for about a two week period before he came in. Now you can pin these symptoms on many things in the central nervous system and I prefer to wait a few minutes before I tell you what I believe they are from. On the morning of admission they noticed he had difficulty in walking and fell to the left. He also became nauseated vomited and then came to the hospital. Past history as given is very brief abdominal pains for the last three or four years. There is no description of character location et cetera so that one has to speculate about these. He had had a poor appetite for a year and had eaten mainly canned food. He had been overseas in Korea for awhile and then in Germany. Then there is the significant statement that he had not indulged in alcohol.

Now it seems to me that this man had some sort of liver disease tied up with spleen involvement and hematologic disorders. The first question is does he have cirrhosis? Well he is 35 which is young for cirrhosis. Generally the age according to Cecil and Loeb<sup>1</sup> is from 45 to 65. There are many causes of cirrhosis and diagnostic tables give between 8 and 12 causes. Laennec's cirrhosis which is the most common can be caused by many things among them toxins such as carbon tetrachloride and phosphorus. Alcohol is implicated in only about 50 per cent and less than 10 per cent have a history of hepatitis. Usually however there is no known cause. It is true that in the Orient malaria and other enteric diseases will give a Laennec type of cirrhosis but there is no history that he developed any of this in Korea. There are endocrine changes which occur in Laennec's cirrhosis resulting in a sparseness of hair and sometimes gynecomastia and testicular atrophy. The reason presumably is that the liver cannot detoxify circulating estrogens or at least does so imperfectly.

It is interesting that the signs initially can be very vague and can last for several years. Nausea, vomiting, and vague abdominal pain are very common. There is often a low grade fever. This man incidentally did not have fever. There is often vomiting, there is weight loss. Jaundice is seldom a conspicuous feature in Laennec's cirrhosis. The bilirubin while it may be slightly elevated is often quite normal in many patients until they go into complete liver failure. Two thirds of the patients with Laennec's cirrhosis have a spider angioma which this individual had on the back of his neck. Some have scanty body hair and ascites while it occurs, is not very common until the disease is fairly advanced. If you can feel the liver and you can feel it in only about half of the cases it feels knobby and is tender. In one series the spleen was palpable in 55 out of 124 cases, and the splenomegaly is due to portal obstruction. Clubbing of the fingers also can occur in cirrhosis. It is not common and is seen in possibly 15 per cent of the cases. Bleeding is a considerable problem and very common in cirrhosis. But it is almost always bleeding from the gastrointestinal tract—either hematemesis or melena—and probably due to the portal hypertension that develops. It also is due to decreased prothrombin, fibrinogen and globulin all of which are made in the liver. The flocculation and thymol turbidity tests are usually positive. There is a decrease in albumin and an increase in globulin and a persistent decrease in albumin is taken as a bad prognostic sign. There is also a macrocytic anemia. You do not necessarily get urobilinogen or bilirubin in urine in cirrhosis, and this patient did not have it.

Briefly to mention other causes of cirrhosis there is postnecrotic cirrhosis which, as you know follows hepatitis perhaps 5 per cent of all cases of cirrhosis are of this type. I do not think this man had a postnecrotic cirrhosis because he had no history of having hepatitis, although it is a possibility that he could have had an anicteric hepatitis. These people when sick are usually quite jaundiced however, and I think this would rule it out. Also they frequently have recurrent attacks of hepatitis which this patient did not have. There is the cirrhosis of hemochromatosis. Seventy five or 80 per cent of these people have diabetes and are between the ages of 40 to 60 years. There is biliary cirrhosis. Generally these people are quite jaundiced, and I believe this rules out this type. There is a cirrhosis due to syphilis, he had a negative serologic test. There is a cirrhosis due to parasites, such as *Schistosoma* he was in Korea and so it is a possibility. I do not think it is too likely however because he did not have fever, chills or signs of an acute infection which is usually found in a parasitic type of cirrhosis. There is the cirrhosis of hepatolenticular degeneration or Wilson's disease. There is finally a cirrhosis which is possible on the basis of cardiac disease he had no history of cardiac disease.

To get back to our patient I think it is quite likely that he had a cirrhotic liver. I do not know the specific cause and I will simply

glottis and difficulty with respiration. An airway was put in place and he was placed in an oxygen tent. The patient died on 14 April 1956 at 1455 hours.

### DISCUSSION

Docto Schneck. I think we can begin by first looking at the only x ray of any significance. This simply shows an enlarged spleen which was palpable in the initial physical examination and through the hospital course. This man was 35 years old which is significant because that is fairly young to have a fatal illness of the character that his apparently was. He came in on 9 April and was unable to give a good history. There could be several reasons for this inability to speak: coma, thickening of speech, confusion, or many others. I saw this man one night two days before he died and from my observation would presume that confusion was the main reason for his not being able to give a good history. Most of the history was obtained from friends and relatives who observed staggering gait, vertigo, and troubles of intellect in the patient for about a two week period before he came in. Now you can pin these symptoms on many things in the central nervous system and I prefer to wait a few minutes before I tell you what I believe they are from. On the morning of admission they noticed he had difficulty in walking and fell to the left. He also became nauseated, vomited, and then came to the hospital. Past history as given is very brief: abdominal pains for the last three or four years. There is no description of character, location, et cetera, so that one has to speculate about these. He had had a poor appetite for a year and had eaten mainly canned food. He had been overseas in Korea for awhile and then in Germany. Then there is the significant statement that he had not indulged in alcohol.

Now it seems to me that this man had some sort of liver disease tied up with spleen involvement and hematologic disorders. The first question is: does he have cirrhosis? Well, he is 35, which is young for cirrhosis. Generally the age, according to Cecil and Loeb,<sup>4</sup> is from 45 to 65. There are many causes of cirrhosis and diagnostic tables give between 8 and 12 causes. Laennec's cirrhosis, which is the most common, can be caused by many things among them toxins such as carbon tetrachloride and phosphorus. Alcohol is implicated in only about 50 per cent and less than 10 per cent have a history of hepatitis. Usually, however, there is no known cause. It is true that in the Orient malaria and other enteric diseases will give a Laennec type of cirrhosis, but there is no history that he developed any of this in Korea. There are endocrine changes which occur in Laennec's cirrhosis, resulting in a sparseness of hair and sometimes gynecomastia and testicular atrophy. The reason presumably is that the liver cannot detoxify circulating estrogens or at least does so imperfectly.

It is interesting that the signs initially can be very vague and can last for several years. Nausea, vomiting, and vague abdominal pain are very common. There is often a low grade fever. This man incidentally, did not have fever. There is often vomiting, there is weight loss. Jaundice is seldom a conspicuous feature in Laennec's cirrhosis. The bilirubin while it may be slightly elevated is often quite normal in many patients until they go into complete liver failure. Two thirds of the patients with Laennec's cirrhosis have a spider angioma, which this individual had on the back of his neck. Some have scanty body hair and ascites while it occurs, is not very common until the disease is fairly advanced. If you can feel the liver and you can feel it in only about half of the cases it feels knobby and is tender. In one series the spleen was palpable in 55 out of 124 cases and the splenomegaly is due to portal obstruction. Clubbing of the fingers also can occur in cirrhosis. It is not common and is seen in possibly 15 per cent of the cases. Bleeding is a considerable problem and very common in cirrhosis. But it is almost always bleeding from the gastrointestinal tract—either hematemesis or melena—and probably due to the portal hypertension that develops. It also is due to decreased prothrombin, fibrinogen and globulin, all of which are made in the liver. The flocculation and thymol turbidity tests are usually positive. There is a decrease in albumin and an increase in globulin and a persistent decrease in albumin is taken as a bad prognostic sign. There is also a macrocytic anemia. You do not necessarily get urobilinogen or bilirubin in urine in cirrhosis and this patient did not have it.

Briefly to mention other causes of cirrhosis there is postnecrotic cirrhosis which, as you know, follows hepatitis, perhaps 5 per cent of all cases of cirrhosis are of this type. I do not think this man had a postnecrotic cirrhosis because he had no history of having hepatitis, although it is a possibility that he could have had an anicteric hepatitis. These people when sick are usually quite jaundiced however, and I think this would rule it out. Also they frequently have recurrent attacks of hepatitis which this patient did not have. There is the cirrhosis of hemochromatosis. Seventy five or 80 per cent of these people have diabetes and are between the ages of 40 to 60 years. There is biliary cirrhosis. Generally these people are quite jaundiced and I believe this rules out this type. There is a cirrhosis due to syphilis he had a negative serologic test. There is a cirrhosis due to parasites such as *Schistosoma* he was in Korea and so it is a possibility. I do not think it is too likely however because he did not have fever, chills or signs of an acute infection which is usually found in a parasitic type of cirrhosis. There is the cirrhosis of hepatolenticular degeneration or Wilson's disease. There is finally a cirrhosis which is possible on the basis of cardiac disease he had no cardiac disease.

To get back to our patient I think it is quite a cirrhotic liver. I do not know the specific cause.

in 300 cerebrovascular accidents How common is cerebellar artery occlusion? Not too common but there are usually characteristic symptoms There are three main arteries that go to the cerebellum the superior cerebellar the anterior inferior cerebellar and the posterior inferior cerebellar arteries I do not think that this man's symptoms fit any of the syndromes which are described because loss of pain and temperature sensations Horner's syndrome and vocal cord and palatal paralysis usually are present

Did he have a tumor? I think he did because the symptoms fit those given by an expanding lesion and are usually rapidly progressive I think this was a metastatic tumor The symptoms are rapidly progressive in metastatic tumor Headache in cerebellar tumor is extraordinarily common This man complained bitterly of severe headache which was not relieved by any analgesics Xanthochromic spinal fluid is found frequently in cerebellar tumors without evidence of gross bleeding Frequently there is a choked disk but this man did not have one Of course there is pressure on the brain stem I think that is what was happening to this man I think his terminal episode when he became generally flaccid when he developed nuchal rigidity and respiratory difficulty was herniation of the medulla down through the foramen magnum In tumor within the brain there is generally as I said an increased pressure I do not know if he had one or not for there is no mention of this There is often an increased protein and normal cell count in the cerebrospinal fluid I do not think he had a primary tumor because they are much more common in children and I could not tie it to his liver and spleen disease with a primary tumor

I do not think he had aneurysm which is also an expanding lesion It gives more cranial nerve symptoms than he had and generally occurs in the base of the brain rather than within the substance of the brain Visual field defects are more prominent I do not think he had a brain abscess although this is a diagnosis which frequently is made only at autopsy You would think that at some time he would have had an episode of fever or chills or some signs of infection and I do not know how you could tie up these other diseases with a brain abscess

So far I have made two diagnoses cirrhosis and congestive splenomegaly I also said that he had tumor within his brain and it is possible he had metastatic tumor with bleeding also in his cerebral hemispheres But I have not located the primary tumor Now does he have a primary liver tumor? Well this is a very rare bird It occurs mostly in the Orient where it accounts for about 10 to 20 per cent of primary tumors There are two types There is the hepatoma which is a widespread or diffuse tumor and constitutes 80 to 90 per cent of all primary hepatic tumors and there is the cholangioma which is primarily a biliary canaliculus tumor There is generally pain over the liver and an enlarged liver it is seen in older people but the symptoms are like

cirrhosis particularly if it is a hepatoma. Does he have a silent tumor somewhere in his abdomen possibly the body of the pancreas? I could not say.

I think I will stop here and say that my diagnoses are cirrhosis of the liver with possibly a hepatoma or some other malignancy within the abdomen, cerebellar metastasis primarily to the left cerebellum and possibly to the cerebral hemispheres and congestive splenomegaly.

Doctor Favelle: I would like to mention that the spinal fluid did contain blood besides being xanthochromic.

Doctor Strickland \*: The point I want to raise is whether a cerebral arteriogram under local anesthesia could have been performed to establish the exact cerebellar lesion. It probably was a posterior cerebellar artery thrombosis.

Doctor Grabb \*: I think that abdominal pain, splenomegaly, anemia, and central nervous system disturbances are frequently seen in acute intermittent porphyria and this could be the case in this patient.

Doctor Schneck: This patient did not have very severe pain anywhere besides the terminal headache, or at least it is not mentioned. He had no paralysis and no weakness except terminally. These are quite major symptoms in porphyria. As far as the posterior cerebellar artery syndrome is concerned the onset usually is sudden, although it can come on slowly. There are sensory changes which are quite marked and this patient did not have them. He did not have Horner's syndrome. He had no loss of pain and temperature sensation. I do not think I could include this in the diagnosis.

Doctor Bortz \*\*: I would like to make a few comments on cerebellar disease. I think there are at least four significant symptoms in this patient that cannot be accounted for by cerebellar disease. These are the changes in intellect, the nuchal rigidity, the convulsions, and the pyramidal signs.

It has been recently reported<sup>3</sup> that there is a leukemia with a normal bone marrow in the preleukemic state. This is usually the monocytic type that can progress rapidly. With leukemia of this type we see splenomegaly and pancytopenia. In fact most of these patients in the preleukemic state are first seen with pancytopenia. I would also consider this diagnosis.

Another point I would like to mention is the cavernous transformation of the portal vein. This is one of the causes of Banti's syndrome. It is usually seen in young patients. They often have the same abnormal liver function tests as this patient had.

---

Capt. William M. Strickland, USAF (MC), Surgical Service.

Capt. William C. Grabb, USAF (MC), Surgical Service.

Capt. Alan I. Bortz, USAF (MC), Medical Service.

The final episode however in our patient was most likely due to bleeding although a tumor in the central nervous system is certainly a possibility

Doctor Strickland: In patients with cavernous transformation of the portal vein who have been operated on cirrhosis has been very minimal because the arterial blood supply was still good There are difficulties due to gastro-intestinal hemorrhage and portal hypertension in this disease

Doctor Schneck In regard to the comment about cerebellar disease it is perfectly true that in general we do not have convulsions and nuchal rigidity in pure cerebellar disease However in this case these symptoms were only seen terminally and they could be due to herniation of the cerebellar tonsils or to a terminal bleeding episode Dulling of intellect however is seen in cerebellar disease

#### Clinical diagnoses

- 1 Cirrhosis of the liver
- 2 Hypersplenism
- 3 Secondary thrombocytopenia
- 4 Central nervous system bleeding

#### Dr Schneck's diagnoses

- 1 Cirrhosis of the liver
- 2 Malignancy in abdomen with cerebellar and cerebral metastasis
- 3 Congestive splenomegaly

#### PATHOLOGIC FINDINGS

Dr to Czernobylsky Significant gross findings of the post mortem examination were as follows

Scattered areas of ecchymosis were present on both arms Ankles showed grade 1 pitting edema There was a brown discoloration of the lower parts of both legs The mediastinal and chest organs were not remarkable Numerous large tortuous veins were present in the fat of the abdominal wall The peritoneal cavity did not contain any fluid The liver weighed 1115 grams The surface was markedly nodular and brown On cut section the normal architecture was not recognized The whole surface was transformed into a finely nodular gray brown tissue The spleen weighed 530 grams The surface was blue to purple No adhesions were present Cut section revealed a dark purple surface The stomach presented a round indurated lesion at the pylorus on the greater curvature This had the form of an ulcer with elevated indurated borders and measured 1 cm in diameter Both kidneys were enlarged The right kidney weighed 250 grams the left 370 The capsules stripped with ease and no gross abnormalities could be found on cut section The other abdominal organs were not remarkable The brain weighed 1620 grams before fixation A diffuse

subarachnoid hemorrhage involved the whole surface of the cerebrum and on cut section scattered petechiae were present in the white substance of all the lobes. On cut section of the cerebellum the center part the left side and part of the right side presented one large hemorrhagic area with destruction of cerebellar substance (fig 1)

*Figure 1 Hemorrhage in cerebellum.*

The microscopic examination of the liver showed a distortion of the normal architecture. Numerous pseudolobules were seen surrounded by large fibrous bands. Throughout the liver there was an increase in connective tissue proliferation of bile ducts and lymphocytic infiltration in portal areas (fig 2). The liver cells contained a brown pigment, which with special iron stain (potassium ferrocyanide stain) was found to be iron pigment (fig 3). The spleen showed severe congestion and a decreased number of malpighian bodies. A small amount of scattered pigment positive for iron was also found. When stained with the routine hematoxylin and eosin stains, the pancreas was found to be normal. The special iron stain revealed a small amount of iron positive granules scattered within the cytoplasm of many acini and occasional cells in the Langerhans islets (fig 4). All the other parenchymal organs, as well as muscle, were stained with iron stain. The bone marrow contained a small amount of hemosiderin. One cervical lymph node was also positive for hemosiderin. The lesion of the stomach was an early adenocarcinoma which did not penetrate beyond the muscularis mucosae. Microscopic examination of the brain confirmed the subarachnoid hemorrhage, petechial hemorrhages throughout the white matter, and a severe hemorrhage and necrosis of the cerebellum. There was no evidence of tumor or vascular occlusions in numerous

sections. On microscopic examination all the other organs including the kidneys, were essentially normal.

Figure 4. Section of pancreas stained for iron. Heavy hemosiderin granules are present in acini. (Potassium ferrocyanide stain,  $\times 950$ )

This case can be classified as an early idiopathic hemochromatosis. The hemosiderin distribution in the liver is characteristic of this disease. The pigment is very abundant and is mainly found within the liver cells and not in the reticulo endothelial system. There is cirrhosis with formation of numerous pseudolobules surrounded by large bands of fibrous tissue. There is hemosiderin in the pancreas although in this case there was absence of fibrosis. The spleen and bone marrow only have a small amount of iron pigment. All these changes have been described in hemochromatosis and cannot be explained on the basis of a simple Laennec's cirrhosis with increased hemosiderin in the liver. The reason that this patient did not develop the typical clinical picture and a very widespread distribution of iron in all the tissues is that he died at an early stage of his disease.

We do have difficulty placing the thrombocytopenia which caused the cerebral and cerebellar bleeding in the picture. Thrombocytopenia

Figure 2. Section of liver showing fibrosis. (Trichrome stain,  $\times 95$ )

Figure 3. Section of liver stained for iron. Hemosiderin is present in liver cells. The distribution is diffuse (Potassium ferrocyanide stain,  $\times 95$ )

sections. On microscopic examination all the other organs including the kidneys were essentially normal.

Figure 4. Section of pancreas stained for iron. Heavy hemosiderin granules are present in acini. (Potassium ferrocyanide stain,  $\times 950$ )

This case can be classified as an early idiopathic hemochromatosis. The hemosiderin distribution in the liver is characteristic of this disease. The pigment is very abundant and is mainly found within the liver cells and not in the reticuloendothelial system. There is cirrhosis, with formation of numerous pseudolobules surrounded by large bands of fibrous tissue. There is hemosiderin in the pancreas, although in this case there was absence of fibrosis. The spleen and bone marrow only have a small amount of iron pigment. All these changes have been described in hemochromatosis and cannot be explained on the basis of a simple Laennec's cirrhosis with increased hemosiderin in the liver. The reason that this patient did not develop the typical clinical picture and a very widespread distribution of iron in all the tissues is that he died at an early stage of his disease.

We do have difficulty placing the thrombocytopenia which caused the cerebral and cerebellar bleeding in the picture. Thrombocytopenia

has been described in hemochromatosis.<sup>4</sup> One explanation would be hypersplenism. The bone marrow obtained at autopsy however does not look like the bone marrow in hypersplenism. In contrast to the peripheral smear obtained during the patient's stay in the hospital the autopsy specimen is hypoplastic. We do think that this latter specimen is more reliable than the first one. In hypersplenism the bone marrow is rather hyperactive and there should be an increase or at least a normal number of megakaryocytes. Although we cannot rule out the possibility of hypersplenism the action of a chemical depressant on the bone marrow should be borne in mind. The severe anemia suggests long standing bleeding which had been going on for some time before his admission. Gastro intestinal bleeding is a good possibility here. Hemochromatosis alone cannot explain an anemia of such a degree.

Doctor Friedman: Were the skin lesions investigated any further?

Doctor Czernobilsky: Unfortunately no skin sections are available.

Doctor Gibson: Did the carcinoma of the stomach originate in an ulcer?

Doctor Czernobilsky: No. There was no evidence of an ulcer in the sections. This was a well-differentiated mucus secreting adenocarcinoma.

#### Pathologic diagnoses

- 1 Early idiopathic hemochromatosis
- 2 Cirrhosis of the liver (due to hemochromatosis)
- 3 Congestive splenomegaly
- 4 Thrombocytopenia (due to hypersplenism or chemical bone marrow depression)
- 5 Subarachnoid, cerebral, and cerebellar hemorrhage due to platelet deficiency
- 6 Adenocarcinoma of the stomach

Capt Herbert S. Friedman, USAF (MC), Chief Urology Service

Capt Bernard F. Gibson, USAF (MC), Chief Surgery Service

## PROGRESS IN AEROMEDICAL EVACUATION

L. RENDER BRASWELL *Colonel USAF (MC)*

**A**EROMEDICAL evacuation today stands at the threshold of new developments. Turboprop and jet-powered aircraft are soon to shrink our planet by shortening travel time, and evacuation activities will increase in comfort, speed, and convenience. Already, the familiar C 47 and C 54 types of patient carriers with their crowded litter tiers have been supplanted in domestic and overseas service by larger, faster, and more comfortable aircraft. Because the military practitioner who must transfer a patient to another hospital has little opportunity to inspect the evacuation aircraft during its short pickup stop, this article describes the scope and the methods of aeromedical evacuation.

Historically, organized evacuation of casualties from the battlefield came well before aviation appeared. Baron Larrey, surgeon in chief of Napoleon's Grand Army, recognized the importance of speedy evacuation and put the first horse drawn ambulance into use. This unit became known as the flying ambulance,<sup>1</sup> because it was so much faster than any other means of transporting the sick and wounded at that time.

Military aviation is older than is generally realized. However, it is well known that the balloon was used in our war between the states for observation and the direction of artillery fire. This soon led to the employment of the balloon as the first air borne patient carrier. Armstrong<sup>2</sup> reported that the first use of aerial means to transport patients occurred during the siege of Paris in 1870. At that time observation balloons removed 160 patients from the city.

An old medical admonition which often appears on the editorial pages of present day medical journals says, in essence "First be sure you do no harm." The need to re-emphasize this ancient principle seems to stem from the introduction of the imposing number of new therapeutic items developed in the past few years—the sulfas, the antibiotics, the antihistamines, and so on through the newest group—the ataractics.

In the aeromedical evacuation operations of the Military Air Transport Service (MATS), this basic safety principle is always kept in mind. In over six years since assuming military patient movement responsibility, MATS has transported well over a third of a million patients losing only two due to aircraft accident. This indicates a flying safety record which is most impressive when compared with the fatality rates for other modes of patient transportation.

Another safety matter of constant concern is communicable disease. It is generally believed that air travel increases the threat of spreading contagious disease. An exposed person might complete a long journey before symptoms appear. Because of modern therapy however very few patients need to be evacuated during the infectious stage of communicable disease. Patients in the MATS transport system have usually been under medical control before we receive them. All are screened by a physician to assure transportability from every standpoint. The physician prescribes any necessary special precautions to apply during flight. He excludes patients in the infectious stage of quarantinable disease. The flight nurse has complete authority to exclude passengers from any patient flight. Standard isolation techniques, such as the use of cubicles and segregation of wastes are applied in flight and continued until arrival at destination hospitals.

Substantial numbers of patients with pulmonary tuberculosis are still transported. An observation which tends to confirm that our defenses against communicable disease afford the patients and medical teams protection consistent with best present-day practice was made recently by a senior Public Health Service medical officer who made a transatlantic air evacuation flight to observe our methods of handling tuberculous patients. After the flight he stated "With the types of tuberculous patients that were being evacuated precautions taken while in transit seemed to be quite adequate both as to their individual care and to minimize hazards of infection of others patients or attendants."

Briefly, the system operates as follows. Patients from overseas travel by MATS aircraft to conveniently located domestic ports of aerial debarkation. Our domestic system moves them from the ports of entry to hospitals designated by the Armed Services Medical Regulating Office.

Movement control centers at specially chosen locations promote effectiveness and economy. These centers are located throughout the transport system. Presently six centers cover medical facilities within their geographical areas in the domestic system. They schedule the movement of patients and effect the most economical utilization of aircraft. They control the dispatching of 30 specially designed flying hospital wards and dispatch

planes consistent with the urgency of the patient movement. If the hospital commander describes the need as urgent, as in a life and death case, the airplane proceeds immediately to move the patient. When the medical facility requests priority movement, the flight is scheduled within 24 hours. Even routine patients must be air evacuated in less than 72 hours.

When MATS became responsible for transporting Department of Defense patients by air, it was forced to use modified cargo aircraft for completion of its mission. In recent years the medical staff has gained membership on the Aircraft Configuration Board, which studies and makes design recommendations for projected aircraft. This membership ensures that specifications for new cargo and personnel transport airplanes incorporate the requirements peculiar to patient transportation. As a result, three new transport types suitably adapted at time of delivery have since joined the MATS fleet: the four engine Douglas Liftmaster (C-118), which flies patients from Europe to the United States, the four engine Boeing Stratocruiser (C-97), which flies the Pacific routes, the four engine Lockheed Super Constellation (C-121C), which covers the southern routes to Puerto Rico and Panama, and the two engine Convair (C-131A), which operates within the continental limits of the United States. This last airplane demonstrates two significant "firsts." The Convair is the first to come from the factory especially constructed for patient transportation. As employed in MATS, it is the first airplane to be wholly restricted to aeromedical evacuation use. It incorporates the features that many years of extensive observation and experience have proved essential.

Some of these features, which now are also built into the other new transports mentioned above, are as follows. Vertically suspended litter assemblies may be adjusted to permit variable spacing, allowing patients to be more accessible to the medical crew, with improved ventilation and heating (fig. 1). Adjustable, suspension spacing permits maximum or minimum loading and better cushioning against normal flight motion and vibration. Modesty curtains, with rods appropriately fixed, may be completely drawn around each litter or each tier of four litters (fig. 2). The cabin heating system can cope with fluctuating temperatures and distributes heat uniformly throughout the cabin. Fresh air vents facilitate rapid air exchange. The exterior coating of fuselage, a solar heat-resistant paint, reduces cabin temperatures while on the ground. Interior insulation reduces the noise level within the cabin. Rheostated interior lighting is sectionalized. Lighting of desired intensity may be supplied individual litter tiers for patient care, while tinted windows reduce sun glare.

*Figure 1 Interior of C-131A (Convair) showing hospital ward appearance and depicting adjustable litter assemblies rearward facing seats, sectionalized lighting and chest respirator equipment.*

Rearward facing seats are able to withstand high decelerative forces enhance comfort and safety. They are light easily removable and may be stowed thus permitting flexibility in loading with litter patients. Medical personnel are seated so as to obtain the best view of their patients. Flight and medical crew members are accommodated with rest facilities adequate for long trips.

The interior of the aircraft has stainless steel or aluminum fittings which are easy to clean and painted so as to present a cheerful hospital ward atmosphere. A scuff board extends from the floor to window level. The deck covering further contributes to the ward atmosphere yet it can sustain the wear of capacity loads and has a nonskid safety surface. Because the cabin is

*Figure 2 Interior of C-131A (Convair) showing cockpit in background rearward-facing seats and compartmented litter tiers with adequate space for nursing care and patient comfort in flight*

pressurized elaborate oxygen systems are dispensed with, and low pressure walk around kits are used for therapy or emergency. Medical personnel communicate with patients or flight crew over a modern intercom system equipped with loudspeakers.

The crew enter and exit at the front of the aircraft, while patients board and debark at the rear, away from the confusion and noise of ground operations.

The new MATS galley, which will fit into any MATS transport, includes an electrical warming oven, hot cups, and circulating air refrigerator (fig 3). This galley is used to serve patients with precooked frozen meals, which are preferred for our purposes. The oven assembly is removable for cleaning or servicing.

Until recently, one of the major problems had been the movement of patients in respirator equipment. Because the large tank-type respirator weighs around a thousand pounds and operates

*Figure 1 Interior of C 131A (Convair) showing hospital ward appearance and depicting adjustable litter assemblies rearward facing seats, sectionalized lighting and chest respirator equipment*

Rearward facing seats are able to withstand high decelerative forces enhance comfort and safety They are light easily removable and may be stowed thus permitting flexibility in loading with litter patients Medical personnel are seated so as to obtain the best view of their patients Flight and medical crew members are accommodated with rest facilities adequate for long trips

*Figure 4. Portable full body half tank respirator containing patient and attended by a flight nurse and medical corpsman. Hand operated bellows demonstrated by corpsman.*

For air terminal ground operations a multiple litter ambulance has been developed, being a modified commercial passenger bus fitted with the airplane type litter assemblies. A capacity of 16 litters thus greatly reduces the number of field type ambulances required at air terminals. This bus ambulance with "walk in" rear doors speeds loading and unloading, requires few attendants, and provides a more comfortable ride than the field type ambulance. Easily removable airplane type seats impart flexibility of loading arrangements because they allow the vehicle to be used as an ambulatory patient carrier and/or quickly converted to litter patient transportation as required.

Standard walk up ramps, now being service tested, eliminate the use of stairs and forklifts and adjust easily to airplane loading doors of differing heights. This device speeds loading and provides smoother handling of litter patients. Research continues into other types of patient loading apparatus, including a lift which is carried in the aircraft and operated by a hand winch. This lift, still experimental, is somewhat awkward but could be used in an emergency when no other equipment is available. tel

*Figure 3 MATS flight nurse uses a refrigerator and electrical warming oven in galley from which patients are served precooked frozen meals in flight*

on normal 110 volt alternating current it presented many loading and operating difficulties. The answer supplied by the Air Force School of Aviation Medicine, Randolph Field, Tex., is a portable full body half tank respirator. This unit has demonstrated by vital capacity measurements that it can provide adequate ventilation in totally apneic patients. Operating normally on regular household current, it weighs less than two hundred pounds and may be easily handled by a few people. The military metropolitan type ambulance will accommodate it where it operates from its own batteries. Loading aboard the aircraft no longer presents a major problem. In the airplane it fits easily into a normal litter tier and with its rectifier it operates from the 24 to 28 volt aircraft current. Should all power operation fail, the hand-operated bellows maintain passive respiration at any desired pressure (fig. 4).

Also modified for operation within the aircraft are other hospital items such as aspirators, incubators, and resuscitators. Added to this is a compact new nursing kit evolved and developed through experience, providing all medications normally required for in-flight nursing care.

In regard to survival equipment, the latest type of life vest designed to our specifications will float a patient wearing any type of cast and has a helicopter harness for easy pickup. It is easy to slip on and may be worn comfortably during an entire trip. Its fluorescent red color makes it easier to see from the air than the previous standard chrome yellow or orange.

*Figure 4. Portable full body bellows respirator containing patient and attended by a flight nurse and medical corpsman. Hand operated bellows demonstrated by corpsman.*

For air terminal ground operations a multiple litter ambulance has been developed, being a modified commercial passenger bus fitted with the airplane type litter assemblies. A capacity of 16 litters thus greatly reduces the number of field type ambulances required at air terminals. This bus ambulance with "walk in" rear doors speeds loading and unloading, requires few attendants, and provides a more comfortable ride than the field type ambulance. Easily removable airplane type seats impart flexibility of loading arrangements because they allow the vehicle to be used as an ambulatory patient carrier and/or quickly converted to litter patient transportation as required.

This device speeds loading and provides smoother handling of litter patients. Research continues into other types of patient loading apparatus, including a lift which is carried in the aircraft and operated by a hand winch. This lift, still experimental, is somewhat awkward but could be used in an emergency when no other equipment is available.

There is also a forced air cooler to augment aircraft air conditioning systems during stops for patient loading in tropical climates. Combining these innovations in reliable aircraft with the services of well trained experienced flight nurses and medical corpsmen a load of patients can be successfully transported from Tokyo to Washington in less than 96 hours. This is routine now a dozen times a month.

### SUMMARY

Aeromedical evacuation merits understanding on the part of participating physicians now that the sciences of medicine and aviation have united to produce both efficient carriers and workable techniques. Preventive medicine practices minimize the danger of spreading communicable disease by air evacuation. Flight surgeons are able to participate in the design of MATS transport planes. Study and experience have produced a substantial list of desirable characteristics and equipment for patient carrying aircraft which are included in present air evacuation planes and programmed for future designs. A bus ambulance and a proposed standard loading ramp improve ground handling of patients. The new portable respirator accompanied by a highly specialized medical team assures the safe world wide transfer of poliomyelitis patients. Organizational progress guarantees close integration of patient movement control centers, medical teams, air crews, aircraft, and ultimately of the entire evacuation activity. The benefit to the individual patient as illustrated by the many military evacuees enhances and promotes the broader Army, Navy, and Air Force programs of military medical care. Finally experience has proved that a patient who can be moved by any means can be safely and quickly transported by air.

# PSYCHOTICS WHO COMMIT OFFENSES PUNISHABLE BY COURT-MARTIAL

Recommendations for Their Early Diagnosis and Treatment

ROBERT L. NELSON *Captain MC USAR*

**E**ARLY diagnosis and treatment of psychosis is of great importance regardless of the circumstances. It is a universal finding that the sooner intensive treatment can be established, the more favorable the therapeutic results. Early diagnosis becomes of even greater importance if failure to establish the diagnosis subjects the patient to prolonged and severe psychologic trauma which may make successful treatment impossible and give the illness a chronic character.

Such a situation exists when a psychotic member of the Army commits an offense punishable by court-martial, and diagnosis has not been established. If the diagnosis of psychosis is not made at the time of or shortly after the offense, the individual is subjected to the psychologic trauma of confinement, court-martial, and sentence. The sentence may include further stockade or disciplinary barracks confinement, fines, and dishonorable discharge. A perhaps even greater trauma is the attitude of society toward the individual who has committed an offense and is considered responsible for his actions. Delays involved in court-martial procedure can at times be prolonged and this may greatly add to the potential of the psychosis for becoming chronic.

Each year this hospital receives many psychotic patients on prisoner status. As officer in charge of the psychotic prisoner patients, I have had the opportunity to observe and evaluate many patients who would have benefited from earlier diagnosis of their psychosis, had this been possible. This article deals with findings on five patients who had undergone general courts martial, that demonstrate in the extreme the need for early diagnosis. Recommendations are made which, it is believed, will be of value in establishing early diagnosis in similar cases. The five patients selected had the following in common:

1 All had received general courts martial, were found guilty, and had begun serving the confinement portion of their sentence.

From Valley Forge Army Hospital, Phoenixville, Pa. Dr. Nelson is now at Harvard University, Dept. of Hygiene, 15 Holyoke St., Cambridge.

2 All were referred to this hospital when psychiatric observation following court-martial revealed the presence of a schizophrenic reaction

3 All were presented to a Board of Medical Officers at this hospital which determined that each one had been psychotic at the time of offense and court martial

4 Medical Board recommendations that unexpired portions of sentences be remitted and dishonorable discharges be revoked were approved and carried out by the Department of the Army

5 All failed to respond to treatment at this hospital were considered to have chronic schizophrenic psychoses and were discharged to civilian mental institutions for continued treatment

The following case histories summarize the clinical data of each of the five patients

### CASE REPORTS

#### Case 1

*Past history* The patient was a 21 year-old single white man His father aged 53 worked for the Fire Department and later for the Post Office The mother aged 45 worked solely as a housewife Both parents were described as being very strict This was more marked in the father who was extremely interested in military history and was a rigid disciplinarian with all the children The patient was the oldest of five siblings He was reared in a large city attended public school and quit at the age of 16 when he was in the 10th grade He then joined a drum and bugle corps and prior to entering service became increasingly interested in historical military figures He always had a limited social life and avoided relating himself closely to anyone There were no serious past illnesses

*Present illness* From early adolescence the patient was withdrawn and unable to have a trusting warm relationship with others including his immediate family He entered the Army at the age of 17 After completing basic training he received demolition training and was then sent overseas Shortly thereafter he became increasingly preoccupied with military concepts and was extremely impressed by efficient military regimes of the past He became critical of the American Army and frequently spent time on duty pretending he had no relationship to the Army By the time he had been overseas one year he began to feel Army authorities were suspecting him of being a communist and were planning ways in which he could be trapped and sentenced to the stockade or prison He believed papers referring to himself as a spy were purposely left about on the desks of important Army authorities

After being overseas two years he was court martialed for being found out of uniform while off duty and breaking a curfew regulation While serving stockade sentence he gradually became concerned about

the possibility of having syphilis, despite the lack of any signs or symptoms of this disease. He requested that a blood test be made and, because of an exaggerated fear of the blood-taking process, asked that Amytal Sodium (brand of amobarbital sodium) be given him prior to the test procedure. This was refused and he was instructed to go ahead with the blood test without sedation. He refused this order and received a second court martial with additional sentence.

While serving sentence the patient suddenly became excited, disrupted furniture in the stockade and attempted to escape confinement. When questioned regarding this by the officer in charge of his confinement, he again disobeyed a direct order and was court-martialed with further increase in sentence time. While still in confinement overseas he made a suicidal attempt and was seen briefly in psychiatric consultation. He was transferred to a disciplinary barracks in the United States where initial evaluation revealed the presence of disturbed paranoid ideation. Arrangements then were made for his transfer to this hospital with a diagnosis of schizophrenic reaction, paranoid type.

At this hospital he continued with psychotic ideation, continually interpreting all hospital activities as part of an investigation to make further charges against him. Affect was inappropriate; he remained aloof from patients and personnel and made repeated inappropriate verbalizations. He failed to respond to treatment which included a series of 16 electroconvulsive treatments. He was presented to a Board of Medical Officers which agreed with the following diagnosis: Schizophrenic reaction, paranoid type, chronic. Manifestations by inappropriate affect, unrealistic behavior and gross delusions.

## Case 2

**Past history.** The patient was a 23 year old single white male, father aged 65, had steady employment as a construction worker, mother was living and in good health. The patient had no siblings. He was reared in a large city, attended public school, quit school at age 16 while in the 10th grade. He worked as a shipping clerk for about one year as a shipping clerk. He was discharged from this period of employment. There were no other significant events.

**Present illness.** At the age of 17 he became extremely seclusive. Coincident with this was the discovery of a testicular varicocele. He was strongly opposed to surgery and would not consent. He remained in his room, refused contact with all others, refused to eat, and continually peered out the windows and doors, often calling him names in passing. He was hospitalized when food was taken to his room. He was allowed to continue in this manner.

19 he was finally persuaded to have a varicocelelectomy and following this he became even more withdrawn seclusive and suspicious To the great surprise of the family he responded to a letter from a friend wondering why he had not been in service and also responded to his draft call by going down for Army induction

While in basic training he felt strange and apart from others Outside the barracks he felt naked and as though others were watching him He felt that they were attracted to his physique and mannerisms and at the same time repulsed He completed basic training and was sent overseas There his symptoms intensified and he felt a strong drive to avoid the stares and implied accusations of those about him Motivated by these feelings he cut his wrists He told officials that it was not a suicide attempt but an attempt to avoid service By saying this he felt his family would not know of his disturbed feelings He was court martialled and transferred to a disciplinary barracks in the United States where initial psychiatric evaluation revealed withdrawal suspiciousness and sexual concerns The diagnosis of schizophrenic reaction was made and he was transferred to this hospital

Here he was withdrawn and hostile and revealed paranoid ideation and grandiosity He was only partially oriented and misinterpreted the remarks and gestures of others on the ward at times this led to hostile physical outbursts He also continued with grandiose ideation feeling himself capable of supreme accomplishment in the fields of education and entertainment Affect was continually flattened and inappropriate He failed to respond significantly to therapy He was presented to a Board of Medical Officers which agreed with the following diagnosis Schizophrenic reaction not elsewhere classified chronic severe manifested by prolonged period of withdrawal from reality beginning at age 17 paranoid ideation grandiose unrealistic self conceptions and suicidal attempts

### Cd e 3

*Past history* The patient was a 21 year old single colored man His father is believed to be dead and the patient had no memory of him He remembered the death and burial of his mother but was unable to recall dates His parents having died when he was quite young the patient was placed in an orphanage where he continued until several years before entering service He was the second of four siblings having two brothers and a sister all believed to be in good health He attended a school for retarded children and is not believed to have finished any school year After leaving school he worked briefly at manual jobs but had no steady employment and rarely engaged in productive activity There were no serious past illnesses

*Present illness* As noted above the patient failed to make a productive adjustment in school or work For several years prior to entering service he drank to excess and engaged in disturbing homosexual activity After completing basic training he was sent overseas There

he was frequently referred to the company sergeant and commander because of excessive drinking and inability to perform his duties, at times being markedly confused. He received a general court martial for disobeying direct orders. A psychiatric report 24 days following court martial indicated a diagnosis of chronic schizophrenic reaction, hebephrenic type. The psychiatrist recommended immediate hospitalization. The patient was hospitalized; a diagnosis of antisocial personality was made, and he was returned to confinement duty where bizarre behavior continued. He was rehospitalized and the diagnosis of chronic schizophrenic reaction, hebephrenic type was again established. He was then transferred to this hospital.

The patient continued to be grossly psychotic in ideation and behavior. He was completely disoriented as to time, place, and person. He assumed bizarre postures and frequently responded to hallucinatory experiences. He required continual direction in regard to all of his personal needs. In relation to others on the ward he displayed inappropriate smiling and laughter. He failed to respond to therapy including a series of 13 electroconvulsive treatments. He was presented to a Board of Medical Officers which agreed with the following diagnosis: Schizophrenic reaction, hebephrenic type, chronic severe manifested by markedly inappropriate affect with excessive unprovoked smiling and laughter, disturbed and confused sexual ideation and behavior, disorientation and hallucinatory experiences.

#### Case 4

*Past history.* The patient was a 17 year old single white man. His mother, aged 33, is believed to be in good health. The father was described as having been an alcoholic and at one time was confined in a state prison on a charge of nonsupport. When the patient was eight years old the parents were divorced and the mother subsequently remarried. The patient is the oldest of seven siblings. One sister is hospitalized with the diagnosis of schizophrenia. Following the divorce of his parents the patient was placed in boarding schools, foster homes, and orphanages for a period of seven years. The patient completed only seven grades of academic work and has never been consistently employed. There is no history of serious past illness.

*Present illness.* At the age of 15 the patient was hospitalized in a state hospital with a diagnosis of schizophrenic reaction, chronic undifferentiated type. He continued under state psychiatric care with three periods of hospitalization during which he received intensive treatment that included subcoma insulin shock, psychotherapy and occupational therapy. He was on conditional release from the state hospital at the time of his entering service at the age of 17.

Throughout basic training the patient was in frequent altercations with other enlisted men. During this period he was court martialed for assault but did not receive a sentence of confinement. At his next assignment he was court martialed for <sup>1</sup>

sentenced to confinement and transferred to a disciplinary barracks. There on psychiatric evaluation he was found to be psychotic experiencing auditory hallucinations and showing inappropriate affect and was considered a suicide risk. A Board of Medical Officers determined that the patient was not free from mental disease at the times of his offense and court martial and was unable to distinguish right from wrong at the time of his offenses. He was transferred to this hospital with a diagnosis of schizophrenic reaction not elsewhere classified chronic manifested by ideas of reference auditory hallucinations distortion of successful thinking and depression.

At this hospital the patient continued to show signs of schizophrenic psychosis including hallucinatory experiences delusional ideation preoccupation with symbolic thought and withdrawal. He failed to respond to therapy and was presented to a Board of Medical Officers which agreed with the following diagnosis: Schizophrenic reaction not elsewhere classified chronic severe manifested by ideas of reference auditory hallucinations severe affect disturbance and withdrawal.

#### Case 5.

**Past history** The patient was a 24 year old single white man. His parents were divorced when he was about four years old and the mother remarried when he was seven. His father worked sporadically as a truck driver and is believed to have been argumentative and a heavy drinker. His mother at the age of 60 still works as a sorter of tags having worked throughout adult life to help support her children. The patient was the second of three siblings. At the time of the parents' divorce the patient was placed in a day nursery. The family financial situation had always been near poverty and at times welfare agencies were needed. He began school at the age of six continuing through the fifth grade. He then attended vocational school for one and a half years stopping at the age of 14. Family financial needs necessitated his withdrawal from school and he obtained work as a truck helper. He had always tended to be a quiet socially withdrawn person who was unusually close to his mother. Throughout adolescence he had a stuttering speech defect and "ear trouble" at the age of 14.

**Present illness** When he was 19 the patient had a brief relationship with a girl that was abruptly terminated by her. From that time he felt that others spread rumors to the effect that he was a homosexual. He became more withdrawn socially. He was inducted into the Army at the age of 21 and after entering basic training felt that those with him at camp were spreading rumors about his engaging in perverted sexual activities. He began a series of three AWOL's motivated by his delusional ideation. While absent from his camp he would return home and remain in seclusion. He believed neighbors were also spreading rumors of a sexual nature. He finally received a general court martial after assaulting a noncommissioned officer and escaping confinement. He was found guilty and transferred to a disciplinary barracks. There

he became acutely excited, destructive of property, and harmful to himself. When finally quieted from this episode, psychiatric evaluation revealed his paranoid delusional ideation and he was transferred to this hospital.

Here his psychotic symptoms, including paranoid ideation, continued. He believed that others on the ward were spreading rumors of sexually perverted acts. He was continually suspicious of other patients and ward personnel and required observation because of assaultive outbursts. He failed to respond to therapy, including 17 electroconvulsive treatments, and was presented to a Board of Medical Officers which agreed with the following diagnosis: Schizophrenic reaction, paranoid type, chronic, severe, manifested by delusions of persecution, ideas of reference, withdrawal, seclusiveness, and acute episodes of aggressive behavior.

### DISCUSSION

Such pertinent data as was equally available on all five of the patients discussed is summarized in table 1 and reveals the following:

1. All were 24 years of age or younger.
2. Three came from homes with disturbed family relationships, having lost one or both parents before the age of eight. The other two showed a degree of family disturbance in that one had a rigid, strict father and the other's family failed to take appropriate action despite five years of gross psychosis.
3. All had psychiatric symptoms prior to entering service, three had had grossly psychotic symptoms, one had schizoid personality characteristics, and one showed a disturbed sexual adjustment, indulged in excessive drinking, and was unable to be productive in any sense.
4. All were privates and failed to adjust to Army life sufficiently to warrant promotion to higher grade.
5. All but one had had more than one court martial. The exception had frequently been referred to his sergeant and company commander because of excessive drinking and inability to perform duties satisfactorily.
6. All had psychotic symptoms prior to court martial.
7. Three received courts martial overseas, after beginning their first overseas assignment. The two who received courts martial in the United States committed their first offenses before completing basic training.
8. All committed offenses that are in some degree peculiar to the military setting, such as refusing medical diagnostic test, disobeying direct orders, and repeatedly going AWOL. In keeping with this, none had a history of a serious civilian offense.

TABLE 1. Summary of case histories of five psychotic general court martial offenders

	Case 1	Case 2	Case 3	Case 4	Case 5
Age when court martialled	21	22	21	17	24
Rank	Private	Private	Private	Private	Private
Army status	Regular Army	Army of United States	Regular Army	Regular Army	Army of United States
Present past history	Father was rigid disciplinarian and bedridden history	Family accepted five years of psychiatric adjustment without referring patient to treatment	Parental death when patient in early childhood. He was then with relatives and no phantasies	Parents present when patient in boarding school orphanage and to father	Parents divorced when patient age 4 spent time in nursery. Marked poverty at home
Psychiatric symptoms prior to entering Army	Limited social adjustment. Tendency to be suspicious of others	Psychotic behavior and attacks for five years	Schizophrenia. Disturbed homosexual adjustment. Excessive drinking. Forfeiture of assets	Psychosis requiring hospitalization one year prior to service	Paranoid delusions for three years
Present offense	Non	None	None	None	None

TABLE 1. *Summary of case histories of five psychotic general court martial offenders—Continued*

	Case 1	Case 2	Case 3	Case 4	Case 5
Total number of courts martial	3	2	1	2	4
General court martial offense	Refused blood test and further disobeyed direct order	Cut wrist in suicidal attempt	Disobeyed direct order	Disobeyed direct order	Assault of noncommissioned officer Escape from confinement
Where court martialled	Overseas	Overseas	Overseas	U.S.	U.S.
Length of time of psychotic symptoms prior to court martial	1 year	5 years	At least several months. Very disturbed adjustment for many years	1 year 5 months	4 years
From court to intensive treatment	1 year 9 months	6 months	6 months	5 months	1 year 6 months
	Schizophrenic reaction paranoid type	Schizophrenic reaction a e c	Schizophrenic reaction hebephrenic type	Schizophrenic reaction n e c	Schizophrenic reaction paranoid type

- 9 The time lapse between court martial and the institution of intensive psychiatric treatment ranged from 5 to 21 months
- 10 All were diagnosed as having schizophrenic reaction—b paranoid type two not elsewhere classified and one hebephrenic type

### RECOMMENDATIONS

A review of the data presented suggests the following recommendations which may aid in early diagnosis and in reducing delay in instituting appropriate treatment

Because all five patients had psychiatric symptoms prior to Army service and all had psychoses prior to committing a general court martial offense it is recommended that induction station and Army physicians be alert to such symptoms The best time for diagnosis to be made and treatment instituted is during routine contacts with physicians before disturbed acting out of svmp toms Any finding of a schizoid characteristic should be thoroughly evaluated with referral to a mental hygiene clinic if indicated

If diagnosis cannot be established earlier the following circumstances at the time of offense warrant a complete psychiatric evaluation

- 1 If there is evidence of disturbed adjustment prior to Army service
- 2 If the offender has failed to make a satisfactory productive Army adjustment This may be indicated by previous courts martial demonstrating a need for rehabilitation
- 3 If the court martial offense occurs before the offender has completed basic training or during his first overseas assignment
- 4 If the nature of the offense resembles a psychiatric symptom for example if the offense is a suicidal attempt or a refusal to carry out a direct order when associated with inability to perform other acts or if the offense shows bizarre motivation

When psychiatric evaluation is performed at the time of court martial it is recommended that it be thorough and complete Patients able to hide psychiatric symptoms from laymen for several years may be able to conceal them from well trained psychiatric personnel during the course of a "routine" interview It is important that the evaluation never become "routine" in any sense The characteristics of any schizophrenic reaction are always individual When possible prolonged direct observation of relations with others Also of great importance is complete evaluation is the patient's past history In the five cases cited all had a history both prior to and during Army service which pointed toward the eventual diagnosis

## SUMMARY

Data on five cases of schizophrenic reaction showed that all had prolonged delays in diagnosis and treatment, all had undergone general court martial, had been found guilty, and had begun sentence, and all were found on subsequent evaluation to have been psychotic prior to and at the time of their offenses. Recommendations are made to aid in early diagnosis and timely institution of appropriate treatment.

---

INTER AMERICAN MEDICAL CONVENTION  
TO BE HELD IN PANAMA CITY

The Second Inter American Medical Convention will be held at the Hotel El Panama in Panama City Republic of Panama 3-5 April 1957, under the sponsorship of the Medical Society of the Isthmian Canal Zone a chapter of the American Medical Association.

The scientific program will be wide in scope and on the order of a state medical convention in the United States. Speakers will be from North and South America with all papers presented in both English and Spanish. Among those who will read scientific papers are Dr. William F. Rienhoff, Jr. on "Surgery in Carcinoma of the Lung," Dr. Hawley H. Seiler on "Surgery of Pulmonary Lesions Other Than Cancer," and Dr. William A. Sodeman on "Amebiasis." "Mass Casualty Management" will be discussed by a team of research workers from Walter Reed and Brooke Army Hospitals headed by Colonel Joseph R. Schaeffer MC USA.

In addition to the scientific papers a full round of entertainment, including deep sea fishing and trips into the interior of Panama is planned for families who accompany the delegates.

For further information address Doctor William T. Bailey, Chairman Publicity Committee Box "E" Balboa Heights Canal Zone.

9 The time lapse between court martial and the institution of intensive psychiatric treatment ranged from 5 to 21 months

10 All were diagnosed as having schizophrenic reaction—two paranoid type two not elsewhere classified and one hebephrenic type

### RECOMMENDATIONS

A review of the data presented suggests the following recommendations which may aid in early diagnosis and in reducing delay in instituting appropriate treatment

Because all five patients had psychiatric symptoms prior to Army service and all had psychoses prior to committing a general court martial offense it is recommended that induction station and Army physicians be alert to such symptoms The best time for diagnosis to be made and treatment instituted is during routine contacts with physicians before disturbed acting out of symptoms Any finding of a schizoid characteristic should be thoroughly evaluated with referral to a mental hygiene clinic if indicated

If diagnosis cannot be established earlier the following circumstances at the time of offense warrant a complete psychiatric evaluation

- 1 If there is evidence of disturbed adjustment prior to Army service
- 2 If the offender has failed to make a satisfactory productive Army adjustment This may be indicated by previous courts martial demonstrating a need for rehabilitation
- 3 If the court martial offense occurs before the offender has completed basic training or during his first overseas assignment
- 4 If the nature of the offense resembles a psychiatric symptom for example if the offense is a suicidal attempt or a refusal to carry out a direct order when associated with inability to perform other acts or if the offense shows bizarre motivation

When psychiatric evaluation is performed at the time of court-martial it is recommended that it be thorough and complete Patients able to bide psychiatric symptoms from laymen for several years may be able to conceal them from well trained psychiatric personnel during the course of a "routine" interview It is important that the evaluation never become "routine" in any sense The characteristics of any schizophrenic reaction are always individual When possible hospitalization is recommended to make possible prolonged direct observation of relationships with others Also of great importance in complete evaluation is the patient's past history In the five cases cited all had a history both prior to and during Army service which pointed toward the eventual diagnosis

Although little in the way of specific knowledge has come down to us regarding the medical side of the War of 1812 and the Mexican War, scraps of information that have filtered down in one way or another, indicate with no reservation, that during both wars, physicians, in addition to their professional duties, were overburdened with additional work of a nonprofessional nature and were too often called upon to perform duties far afield from the practice of medicine. Listen to Surgeon General Thomas Lawson as he writes to the Adjutant General in the year 1840 "I have acted as quartermaster and as adjutant, and have been for months at a time in command of a company of men in the regular Army. I have also commanded a battalion and a regiment of men in the volunteer service, and have led them to a theater of war."

Nor did the situation change materially until the first year of the Civil War, when a Sanitary Commission was appointed, a commission that assumed wide powers and held sway in no menial fashion. Their investigations left them unhappy with the condition of hospitals, the lack of organized transport for the sick and wounded, and a general situation which they interpreted as one of stagnation. Their decision was to institute a reform and to name a new surgeon general.

They chose a young 34 year old assistant surgeon, William Hammond, who had already served with the Army in the far west, gained recognition as a medical writer, and held the chair of anatomy and physiology at Maryland. Hammond rejoined the Army at the outbreak of war. This officer was to be a controversial figure throughout his Army career and even afterward, but there remains no doubt that he brought to his assignment unbounded energy, keen understanding and unusual foresight.

In his annual report for 1862, General Hammond recommended "the establishment of a permanent hospital and ambulance corps, composed of men specially enlisted for duty in the Medical Department, and properly officered, who shall be required to perform the duties of nurses in the hospitals, and to attend the services of the ambulances in the field."

General Hammond cleverly motivated his effort to obtain a hospital corps by pointing out that such a corps would allow several thousand detached men serving in hospitals to return to their own regiments. Still no enlisted corps was granted. But Hammond refused to be stymied easily. He anticipated the nonconcurrence of those to whom his appeal was directed, and asked for civilian nurses and cooks to live in the general hospitals. When this recommendation won approval, he organized a hospital corps for duty in general hospitals. He prescribed uniforms, physical qualifications, discipline, mode of payment, and in every way had himself

a quasi military organization These units were the forerunners of our hospital medical detachments of today

Our next overt report as to the Hospital Corps came in 1887, in the annual report of Surgeon General John Moore, wherein it is noted that "the law to organize the Hospital Corps having been signed by the President transfers of men were being made from the line of the Army as rapidly as possible "

A year later he again commented "The organization of the Hospital Corps is nearly completed 614 privates have been transferred to it from the line 24 of whom were found qualified after examination for the position of acting hospital steward and so detailed 125 vacancies remain 9 for civilian, 10 for privates 81 for acting hospital stewards and 25 for hospital stewards "

Colonel Ashburn might well be quoted again on this subject as follows "This was an event truly great in the history of the Medical Department but its greatness is not apt to be appreciated by the present generation of medical officers whose whole service has been familiar with the work of the highly trained female Nurse Corps which has been part of the Army since the Spanish American War But prior to that war and after 1888 there was only the Hospital Corps It speedily developed a splendid corps spirit, took great interest in its work developed many excellent technical assistants for operating room and laboratory and enabled the medical officers to organize and conduct their hospitals in the (then) most modern manner In the hospital and in the field they rang true "

Little concrete writing is available today as to further exploits of the Hospital Corps Surgeon General Sutherland mentions the blooding of the Corps in the last of the Indian Wars in his report of 1891 In the same year Captain John Van R Hoff Assistant Surgeon in reporting on the battle of Wounded Knee noted "I have heretofore had the honor to submit many reports and suggestions regarding the Hospital Corps under various conditions of service in post camp and field but it was only recently I had an opportunity to see its working under the crucial test of battle It is but faint praise to say that it more than met my expectations

The Hospital Corps continued as an entity of the Medical Department and performed its mission well In the Spanish American War it expanded to almost seven times its size performing creditably throughout the war When it returned to its normal peacetime strength after the war a period of optimism set in due to legislation allowing an increase of 50 per cent in hospital stewards This period lasted only about two years when further legislation eliminated this heartening situation A new basis for Hospital Corps manpower was announced and the "ancient and

honorable title of hospital steward," as Colonel Ashburn rightfully termed it, passed from Medical Department terminology. This marked the close of some one hundred and twenty five years of ancestry in the evolution of the Medical Service Corps.

We now approach the more modern beginnings of your Corps, leaving "ancient" history and drawing near to those times which are not apart from the memory of living people. All that has transpired until this point conclusively demonstrates the need for an ancillary corps within the Medical Department.

In June 1916, anticipating the seemingly inevitable participation of our country in the European War, Congress gave the President authority "to increase temporarily the military establishment," thus providing the legal basis for an ancillary corps within the framework of the Medical Department.

It was evident, almost forty years ago, as it was to be evident in other similar circumstances, that the Medical Department, once embroiled in an extensive war, would face the problem of not having enough medical officers to provide proper professional care to the large numbers of casualties that might be expected. It was logically reasoned that if a group of officers could be obtained to perform the nonprofessional duties of the Medical Department, more physicians would be available to render necessary professional care to the sick and wounded.

General Gorgas, The Surgeon General, recommended the establishment of the Sanitary Corps, and when his recommendation was approved, this Corps became active within the Medical Department in the summer of 1917. The empowering legislation authorized the appointment of "citizens of the United States who are found under regulations established by the Secretary of War to possess special skill in sanitation, sanitary engineering, in bacteriology or other sciences related to sanitation and preventive medicine, or who possess other knowledge of special advantage to the Medical Department."

Obviously, the primary reason for establishing the Sanitary Corps was the crying need of the Medical Department for officers capable of relieving medical officers of administrative duties and certain other nonprofessional medical duties. Another reason existed. When World War I was forced upon us, there was no avenue of approach to a commission for our senior noncommissioned officers of the Medical Department, due to its singular construction. Other branches of the Army had no such restriction, and many senior noncoms were seeking and obtaining commissions in the Infantry, the Quartermaster Corps, the Adjutant General's Corps, and in other branches. Should sizable numbers of our senior noncommissioned officers apply for transfer to other

obtain commissions their skills would be lost at a time when most sorely needed—during the time of buildup, when highly trained cadremen would be most essential. Having the Sanitary Corps at hand eased this potentially dangerous situation considerably and we were able to offer our most capable noncommissioned officers a chance to gain officer status within our own Department.

With the rapid influx of civilians with specialties and skills allied to medicine and highly qualified and trained enlisted men, the Sanitary Corps expanded overnight. These individuals served with distinction throughout the entire war in just about every imaginable position in which their presence could be used. No echelon of the Medical Department was without its share of Sanitary Corps officers from post camp and station through division level and up to the Office of the Surgeon General itself where Sanitary Corps officers were assigned to the Personnel Administrative and Dental Divisions as well as to the Sanitary Division.

The Sanitary Corps was a healthy and long lived organization, a worthy antecedent of your healthy Corps of today. Although it had never gained the status of a regular component of the Medical Department having been constituted for the emergency period of World War I, it managed to remain alive between the two World Wars in Reserve status. Reactivated in World War II, it flourished until its active members and its Reserve component were absorbed in 1947. When it passed from the scene it left behind a record of over thirty years of faithful and dedicated service to the Army and to the nation.

The scattering to the four winds of the officers of the Sanitary Corps in the confusion of the post-World War I demobilization served to pinpoint the continuing need for an ancillary corps within the Medical Department. Surgeon General Merritt W. Ireland in 1920 recommended that such a corps be established and asserted that it should be called the Medical Service Corps. This some 27 years before your present Corps was born. Speaking before a Senate Committee General Ireland said in part: "Then there is another provision that I would like to have considered by the committee and that is the establishment of a new corps in the Medical Department and it can be done without expense and without increasing the number of officers and I think probably with a little saving. The proposition is that we shall have a Medical Service Corps and that it shall be made up of men who have served at least five years as soldiers and at least three years shall have been in noncommissioned officer's grade. At the end of that time after passing a prescribed examination he can be commissioned in the Medical Service Corps. They are going to do the work that we are now doing with highly trained

medical officers, and if allowed, those highly trained medical officers can return to their professional work. This will be an advantage in many ways. It will give encouragement to the members of the Hospital Corps, it will give him a future, and we will get a much better class of men into the Hospital Corps because he sees a majority awaiting him if he can make good."

General Ireland's recommendation for a Regular Army and Reserve Corps of nonprofessional officers was in part adopted. His recommendation that a Medical Service Corps be established was not accepted, but legislation permitting the Medical Administrative Corps was passed in June 1920.

For those of you who do appreciate a "romantic" touch, I might add that General Ireland, in his first year as a member of the Medical Corps, served at Fort Riley, where he had charge of the first company of instruction of the Hospital Corps that was ever organized. The year was 1891. His direct superior officer was a Major John Van R. Hoff, whom I quoted a short time back. It seems to me most appropriate that General Ireland, whose first assignment concerned itself with your antecedent group, should not as spokesman—some thirty years later—in recommending a vitally needed ancillary corps within the Medical Department.

Members of this new Corps had need of their pioneer background. General reductions in the strength of the Army, as well as legislation which appeared to discriminate against them, whittled the size of the Corps nearly in half. Arbitrary limitations as to grade expectancy was a bitter pill to swallow. In common with their Medical Corps associates, members of the new Corps began to feel the burden of "additional duties."

General Ireland now came forward with still another recommendation. He proposed amendment of the National Defense Act to establish a Medical Auxiliary Corps to consist of some 140 officers, *in grades from second lieutenant to colonel*. His idea was to recommission Medical Administrative Corps officers in the new Medical Auxiliary Corps in corresponding grades. The arbitrary restriction as to highest grade would thus be removed, and officers could be promoted on the basis of length of service just as the members of the other corps of the Medical Department were promoted. While it was true that not too many officers on duty at the time the bill was proposed would profit greatly by its passage, it would provide a firm basis for future career personnel, spelling out as it did the appropriate use of such officers.

In his annual report of 1926, General Ireland referring to the limitation of income for Medical Administrative Corps officers states "It has never been understood by this office how so and discriminatory a measure as this crept into the bill."

final days of its passage. It practically means that an officer of the Medical Administrative Corps of long service at present in the grade of first lieutenant and promoted to captain receives no increase of pay. It is proposed that hereafter they be promoted after stated periods of service on up to the grade of colonel. This seems to be of particular importance with reference to the younger men now being commissioned in the Medical Administrative Corps.

In years past many of the enlisted men of the Medical Department looking forward to a commissioned career have sought and qualified for a commission in the line. This bill if enacted will offer to these enlisted men of the Medical Department equal opportunity in their own department and become a big factor in building up the type of enlisted force the Medical Department is trying to develop and urgently needs."

General Ireland's proposed legislation was not enacted. The medical officers continued to be burdened with too much work of a nonprofessional nature. Until his retirement in 1930 General Ireland continued his running battle to increase the numbers of all corps of the Medical Department without success.

In a letter accompanying his last annual report General Ireland paid tribute to the Medical Administrative Corps, praising its usefulness and its over-all operation. Throughout his tenure as Surgeon General he was forever in the forefront of those who tried to help the Medical Administrative Corps and its officers. He did everything that was humanly possible to dissolve the inequities under which the corps labored at that time. Even though little in the way of expanded career incentives was obtained during his stewardship, his willingness to champion the Medical Administrative Corps and its officers and the zealous efforts he put forth in their behalf lifted their morale as nothing else could have done. With the retirement of General Ireland, one of the greatest champions the Medical Administrative Corps ever had, passed from the active scene.

In 1935 a bill to authorize a Medical Auxiliary Corps was again introduced into the House of Representatives. This history and background of this particular bill is somewhat shrouded in mystery; practically all we know about it is that it was introduced by a Representative McSwain. It was analogous to the bill that General Ireland had proposed some time earlier, differing in proposing percentage-wise limitations in the various grades and also in providing for pharmacists and members of other professions allied to medicine to be commissioned in the proposed corps. This bill died in committee.

Both the Regular Army and the Reserve Medical Administrative Corps continued to decrease in size until 1941 when numerous

reserve and National Guard officers were called up for the duration of the emergency. Planning in preparation for possible global war led to the opening of officer candidate schools for Medical Administrative Corps applicants, first at Carlisle Barracks and later at Camp Barkley. I will wager that a goodly percentage of those of you who are listening to me tonight gained your commissions at one or another of these schools, whose graduates were to see service in every corner of the globe.

The Pharmacy Corps, in one sense, could trace its past to a point in time preceding even that of the Sanitary Corps, inasmuch as legislation concerning the utilization of pharmacists in the Medical Department had been proposed in Congress before 1917. Initially opposed to some features of the bill, General Ireland with the passage of a few years became amenable to the inclusion of a "certain number of pharmacists in the Army." They would have fitted very well into his proposed Medical Service Corps of 1920.

Legislation to commission pharmacists in the Medical Department was introduced into Congress in 1935 and passed in June 1936. The National Defense Act of 1920 was amended to allow a maximum of 16 pharmacists commissioned status in the Medical Administrative Corps. The stringency of this act was not recognized immediately, but if it were to be followed, it would preclude appointments other than of registered pharmacists in the Medical Administrative Corps in the future, and would ultimately have reduced the Corps from its authorized total of 72 officers to a total of only 16 officers.

Surgeon General Reynolds, commenting on this legislation in 1936, had this to say: "It is not as drug clerks, primarily or exclusively, that we contemplate the services of these officers, but more with the meaning 'pharmacy' as it is termed in the armies of Continental Europe, where the 'pharmacist' is a highly trained and educated officer who is concerned with practical sanitation, the procurement and development of military medical supplies and equipment, and the technical service in the chemical, bacteriological, serological, and x-ray laboratories."

In 1942 a bill to establish a Pharmacy Corps was introduced by Congressman Carl T. Durham, of North Carolina, in May 1943, it was approved with minor modifications. The President signed it into law in July 1943, and the Regular Army component of the Medical Administrative Corps passed into history after an active life of some twenty-three years. The Reserve component of the Medical Administrative Corps kept its name temporarily. The Pharmacy Corps was absorbed into the Medical Service Corps when that branch came into being in August 1947.

final days of its passage. It practically means that an officer of the Medical Administrative Corps of long service at present in the grade of first lieutenant and promoted to captain receives no increase of pay. It is proposed that hereafter they be promoted after stated periods of service on up to the grade of colonel. This seems to be of particular importance with reference to the younger men now being commissioned in the Medical Administrative Corps.

In years past many of the enlisted men of the Medical Department looking forward to a commissioned career have sought and qualified for a commission in the line. This bill, if enacted, will offer to these enlisted men of the Medical Department equal opportunity in their own department and become a big factor in building up the type of enlisted force the Medical Department is trying to develop and urgently needs."

*General Ireland's proposed legislation was not enacted.* The medical officers continued to be burdened with too much work of a nonprofessional nature. Until his retirement in 1930 General Ireland continued his running battle to increase the numbers of all corps of the Medical Department without success.

In a letter accompanying his last annual report General Ireland paid tribute to the Medical Administrative Corps, praising its usefulness and its over-all operation. Throughout his tenure as Surgeon General he was forever in the forefront of those who tried to help the Medical Administrative Corps and its officers. He did everything that was humanly possible to dissolve the inequities under which the corps labored at that time. Even though little in the way of expanded career incentives was obtained during his stewardship, his willingness to champion the Medical Administrative Corps and its officers, and the zealous efforts he put forth in their behalf, lifted their morale as nothing else could have done. With the retirement of General Ireland, one of the greatest champions the Medical Administrative Corps ever had, passed from the active scene.

In 1935 a bill to authorize a Medical Auxiliary Corps was again introduced into the House of Representatives. This history and background of this particular bill is somewhat shrouded in mystery; practically all we know about it is that it was introduced by a Representative McSwain. It was analogous to the bill that General Ireland had proposed some time earlier, differing in proposing percentage-wise limitations in the various grades and also in providing for pharmacists and members of other professions allied to medicine to be commissioned in the proposed corps. This bill died in committee.

Both the Regular Army and the Reserve Medical Administrative Corps continued to decrease in size until 1941 when numerous

reserve and National Guard officers were called up for the duration of the emergency. Planning in preparation for possible global war led to the opening of officer candidate schools for Medical Administrative Corps applicants, first at Carlisle Barracks and later at Camp Barkley. I will wager that a goodly percentage of those of you who are listening to me tonight gained your commissions at one or another of these schools, whose graduates were to see service in every corner of the globe.

The Pharmacy Corps, in one sense, could trace its past to a point in time preceding even that of the Sanitary Corps, inasmuch as legislation concerning the utilization of pharmacists in the Medical Department had been proposed in Congress before 1917. Initially opposed to some features of the bill, General Ireland with the passage of a few years became amenable to the inclusion of a "certain number of pharmacists in the Army." They would have fitted very well into his proposed Medical Service Corps of 1920.

Legislation to commission pharmacists in the Medical Department was introduced into Congress in 1935 and passed in June 1936. The National Defense Act of 1920 was amended to allow a maximum of 16 pharmacists commissioned status in the Medical Administrative Corps. The stringency of this act was not recognized immediately, but if it were to be followed, it would preclude appointments other than of registered pharmacists in the Medical Administrative Corps in the future, and would ultimately have reduced the Corps from its authorized total of 72 officers to a total of only 16 officers.

Surgeon General Reynolds, commenting on this legislation in 1936, had this to say: "It is not as drug clerks, primarily or exclusively, that we contemplate the services of these officers, but more with the meaning 'pharmacy' as it is termed in the armies of Continental Europe, where the 'pharmacist' is a highly trained and educated officer who is concerned with practical sanitation, the procurement and development of military medical supplies and equipment, and the technical service in the chemical, bacteriological, serological and x-ray laboratories."

In 1942 a bill to establish a Pharmacy Corps was introduced by Congressman Carl T. Durham, of North Carolina, in May 1943, it was approved with minor modifications. The President signed it into law in July 1943, and the Regular Army component of the Medical Administrative Corps passed into history after an active life of some twenty-three years. The Reserve component of the Medical Administrative Corps kept its name temporarily. Pharmacy Corps was absorbed into the Medical Service when that branch came into being in August 1947.

The performance of the Medical Administrative Corps and its officers in World War II has been sufficiently chronicled, it is too well known to require further treatment at this time. Your Corps and its individual officers faced and met responsibility with confidence and efficiency and by the time hostilities were over they were performing creditably almost every type of duty except the actual practice of medicine, dentistry and nursing within the purview of the Medical Department.

General Norman Kirk, sensing the unwieldiness of the administrative groupings within the Medical Department after World War II, recommended the establishment of a single corps which would incorporate the skills and administrative and technical knowledge found in the Sanitary Corps, the Medical Administrative Corps and the Pharmacy Corps. He recommended that it assume the name and be patterned after the corps originally proposed by General Ireland in 1920.

The initial period of regrouping, the overwhelming administrative difficulties which arose and the host of problems allied to your reorganization were met in characteristic fashion by Colonel Goriup, your first chief, and his able assistants. Colonel Goriup and his successor, Colonel Black, did yeoman work in their terms as Chiefs of the Corps. I wish that I had more time to delve into the background of some of the problems these officers coped with and the tremendous effort expended in their solution. I believe we are too near to their work to see it in its true perspective.

I do not wish to seem blunt or brief in speaking of the Korean campaign. The manner of performance of duty of our Medical Service Corps officers is here again too recent to need analysis or comment. I see here tonight many officers whose service in Korea was a service of high distinction. In such circumstances it is not proper to discuss history with men who helped in their own way to make that history.

After this short wandering tour through some of the highlights of the history of your Corps, we reach the present. And what about this Medical Service Corps of today? Or of tomorrow?

Your Corps is headed up by another dynamic officer, Colonel Bernard Aabel, who reflects the high purpose and ability to get things done that characterized the two Chiefs who preceded him. Your senior officers are bastions of strength. On every hand we have junior officers whose performance of duty is superior. One of the nicest things about our present crop of Medical Service Corps officers is that none of them are just "going along for the ride." The Medical Service Corps of today is composed of individuals who are dedicated to the highest principles of the Army Medical Service, the United States Army and this great nation of ours.

But what about tomorrow?

Much as I wish it were otherwise, I have no crystal ball, and I am not able to define the kind of Medical Service Corps that tomorrow will bring to, or require of, the Army Medical Service. I do know that it will continue to offer fruitful careers to qualified men whose interests in life include work in paramedical fields and service to their country, that much will remain unchanged.

Within the past year or so new career incentives and new career opportunities have become available to you. I refer to the careers that have opened for you in such fields as medical intelligence, military missions and particularly in the Logistics Officer Program. In encompassing the whole area of service support, this latter program alone is breath taking in its possibilities. These are optimum times for the advancement of your Army careers. A newer and broader vista of opportunity and promise will open to you in the rich future that beckons to the Medical Service Corps.

Your Corps stands in the unique position of being old enough to have its own traditions, yet young enough to be impressionable. You can gain new life from the reservoir of your past experience that will help you to look forward with the keen vision that tomorrow's problems will demand. If, as the historians say, the Past is Prologue, your past record tells me that your officers will write still finer chapters in your history.

One thought must give us pause in attempting to preview your future. I believe you must heed the injunction made by Secretary of the Army Wilber M. Brucker recently. Secretary Brucker said "We derive great inspiration from the magnificent achievements of yesterday, but unless we translate that inspiration into equally splendid accomplishments today, the American way of life cannot long survive." This challenge will remain constantly with you as you move forward.

## CASE REPORTS

### Oral Surgery Complications Caused by Flight

LUCIAN SZMYD *Major USAF (DC)*

**T**HE extraction of posterior maxillary teeth often necessitates the removal of considerable alveolar bone. Large areas of antral membrane thus may be deprived of bony support. The purpose of this article is to discuss some of the physical factors encountered during flight which may affect the postoperative course of such cases. The case reported here demonstrates the effect of changes in atmospheric pressure created during flight on the Schneiderian membrane of an abnormal sinus following the surgical extraction of maxillary posterior teeth.

When the maxillary sinus is subjected to variations in barometric pressure during flight equilibrium between the pressure within the cavity and atmospheric pressure is established at a rate that depends upon the size of the ostium and the extent of change in barometric pressure.<sup>1</sup> The extent of change in atmospheric pressure depends upon the altitude and the rate of vertical ascent or descent.<sup>2</sup> When the maxillary sinus is normal and the ostium is patent differences in pressure between the air within the sinus cavity and the surrounding atmosphere are brought into equilibrium quickly and uneventfully.<sup>3</sup> Obstruction of the ostium by redundant or hypertrophied tissue, anatomic deformities, polyps, mucus or purulent exudate may delay or prevent equilibration of pressure<sup>4</sup> (fig. 1).

Varying atmospheric pressure changes are created by flight. Operational aircraft fly at altitudes over 40 000 feet and are capable of vertical ascent at rates of 100 feet per second and dive at speeds of 1 000 feet per second. Operational aircraft flying at altitudes exceeding 40 000 feet maintain their cabin pressure at approximately 16 000 to 20 000 feet. Conventional transport aircraft fly at altitudes of 6 000 to 10 000 feet and ascend and descend at rates approximating 10 feet per second. Commercial transport aircraft flying at altitudes exceeding 10 000 feet maintain their cabin pressure at approximately 6 000 to 10 000 feet.<sup>5</sup>

Whenever the antral membrane is exposed or perforated in an oral surgical procedure the patient is always cautioned against

*Figure 1 (A) During ascent any valvular formation within the sinus cavity will prevent the exit of air from the sinus as the atmospheric pressure decreases. (D) During descent and increase of atmospheric pressure similar formations on the nasal side of the ostium will prevent the entrance of air into the sinus.*

**A Ascent**

- A1 V—Developmental flap valve formation of sinus mucous membrane  
 A2 M—Swelling of the mucosa of sinus with flutter valve effect  
 A3 P—Mucosal polypus in sinus constituting a ball valve

**D Descent**

snoezing or blowing of the nose because these acts affect the pressure in the maxillary sinus. This can readily be demonstrated by blowing the nose in the presence of a small perforation of the antral membrane. Air bubbles will be emitted from the perforation site due to the increase in pressure of the gases in the antrum.

The following case illustrates that when the Schneiderian membrane of an abnormal sinus is exposed or perforated following a surgical procedure, the patient should be cautioned not only against sneezing and blowing of the nose, but also against travel.

## CASE REPORT

A 23 year old airman was referred by the ear nose and throat department to the oral surgery service with a large oroantral fistula. Six weeks prior to admission the right maxillary first and second molars were extracted. The patient stated that considerable alveolar bone had been removed in order to perform the extractions and that he was cautioned against blowing his nose or sneezing afterward. Healing was uneventful until the patient took an airplane flight one week after the operation. After landing the patient noted a large mass protruding into his mouth at the extraction site (fig 2). A diagnosis of a herniated antral membrane was made and the tissue was excised. The patient was then referred to the oral surgery service for treatment.

Figure 2 Photograph showing the herniated antral membrane in the right molar area following flight. (Mirror image shows the palatal view.)

Clinical examination revealed an oroantral opening 1 cm in diameter in the area of previous extractions (fig 3). A probe passed readily through the opening into the right maxillary sinus. A large polyp was obstructing the opening but no evidence of drainage from the maxillary sinus was noted. No lymphadenopathy or asymmetry of the face were seen on admission. Roentgenographic examination revealed a generalized opacity of the right antrum (fig 4A).

From clinical and roentgenographic evidence it appeared that three conditions had existed prior to air travel (1) infection of the maxillary sinus (2) lack of bony support for the nasal membrane in the area of the herniation, and (3) a defect in the integrity of the oral mucous membrane in the area of the herniation

*Figure 3 Photograph showing the oroantral fistula.*

Using general anesthesia an orthodox Caldwell Luc approach was used to enter the right maxillary sinus. After the removal of polyps and purulent exudate a nasoantral window was made. The antrum was then packed with iodoform vaseline gauze. The end of the pack was passed into the nasal cavity and the original incision was closed without drainage. After de epithelization of the fistulous tract a subperiosteal palatal flap containing the anterior palatine artery was provided to close the oroantral fistula (fig 5). A surgical acrylic splint which had been constructed prior to surgery was adjusted and inserted.

The postoperative course was uneventful. The denuded area on the palate was completely epithelized and a satisfactory closure of the oroantral fistula was obtained (fig 6). Roentgenographic examination four months postoperatively, revealed that the rig (fig 4B)

*Figure 5 Photograph taken two weeks postoperatively showing the flap over the right maxillary molar area and the denuded area on the palate*

*Figure 6 Photograph taken four months postoperatively showing the successful plastic closure of the oroantral fistula.*

## SUMMARY AND CONCLUSIONS

Changes in atmospheric pressure created during flight may produce undue stress on the antral membrane of an abnormal sinus when it is devoid of bony support

The oral surgeon must be aware of the physical factors encountered during flight which may adversely affect the postoperative course in patients from whom considerable alveolar bone is removed during the extraction of posterior maxillary teeth. In cases where alveolar bone is lost in the vicinity of the antrum, the oral surgeon should obtain roentgenograms to evaluate the sinus. Whenever infection or other abnormalities are noted treatment should be recommended and the patient advised against air travel.

The wisdom of this course is illustrated by a case report which describes the herniation of an antral membrane at the site of a defect in the alveolar bone produced during dental extractions. Infection of the maxillary sinus existed prior to the herniation. If the patient had been warned to avoid air travel the herniation probably would not have occurred.

# Priapism of Unknown Cause

EDWARD C. LEWIS II Lieutenant MC USNR

BENJAMIN F. SCHWARCZ M D

**P**RIAPISM is an uncommon and extremely distressing condition which has not been adequately dealt with in the textbooks. It is usually defined as a state of sustained, painful erection without sexual desire. Priapism may be due to a variety of causes which can be grouped into two general categories—nervous and vascular.

It has long been observed that men hanged by the neck develop priapism. This condition has also been seen in injuries of the cervical cord and, as a rare manifestation, of central nervous system disease such as syphilis and multiple sclerosis. In priapism associated with central nervous system disease, the patients have usually developed associated urinary retention due to interference with the nervous mechanism controlling micturition. Priapism due to vascular causes constitutes by far the largest group of cases. Erection is maintained by thrombosis of the venous channels of the penis.

Thrombosis may result from sickle cell anemia, leukemia, carcinomatous infiltration of the corpora cavernosa, and as a result of trauma to the perineum. Priapism in the younger age group is usually the result of leukemia or sickle cell anemia, while in the older age group it is more apt to be due to carcinoma.

The two following cases are unusual because of the absence of an etiologic factor and the prolonged duration of priapism.

## CASE REPORTS

**Case 1** A 40 year old Negro was admitted to this hospital on 22 August 1951 six days after awakening with an erect penis which had failed to subside. He gave a past history of syphilis which had been treated with arsenicals in 1942. On admission to the hospital his penis was erect and tender but he was able to void without difficulty. Examination revealed no significant abnormalities except for the priapism. Both the corpora cavernosa and the corpus spongiosum were involved. Laboratory studies disclosed no evidence of sickle cell anemia. The patient had a quantitative Kahn of 8 units and spinal fluid complement fixation was 3 plus. An intravenous pyelogram and a roentgenogram of

the chest were normal. A roentgenogram of the spine showed hypertrophic arthritis.

The patient was placed on heparin therapy. Ice bags were applied to the penis and two lumbar sympathetic blocks were done without benefit. On the 19th hospital day, which was 25 days after the onset of priapism, the corpora cavernosa were aspirated with a No. 15 gage needle and then irrigated thoroughly with normal saline solution. Prompt improvement occurred and the priapism subsided within 24 hours. Five days later the patient was discharged, at which time the penis had returned to its normal state and he was again having morning semi-erections.

**Case 2.** A 23 year old white male was admitted to this hospital on 19 December 1953 because of priapism of three days duration. He had had a similar episode two years previously lasting only 8 hours. On admission he was able to urinate and had no dysuria but his penis was painful. A review of his past history contained nothing pertinent to the present illness. Positive physical findings were limited to the penis which was erect and painful to touch. Both the corpora cavernosa and the corpus spongiosum were involved in the erection. Laboratory studies including a complete blood cell count, urinalysis, prothrombin and bleeding times and spinal fluid protein, sugar and colloidal gold were within normal limits. The Kahn test and spinal fluid were negative for syphilis. Roentgenograms of the spine and chest revealed normal findings.

The patient was first treated with heparin and Dicumarol (brand of bishydroxycoumarin) in an attempt to prevent further thrombosis. He was also placed on diethylstilbestrol and an ice bag was applied to his penis. This was of no avail and his condition became progressively worse with more pain and tenderness. On the third hospital day he was given a spinal anesthetic and when this failed to relieve his priapism the corpora cavernosa were evacuated through a No. 16-gage needle and irrigated with normal saline solution. Following this procedure priapism gradually subsided and was completely gone by the seventh post-operative day. Three weeks after aspiration the patient was again *having semi-erections in the morning*. A follow up in April 1956 disclosed that he was still having semi-erections and was able to have sexual intercourse. He had had no further episodes of priapism and had not noticed any deformity of his penis as a result of aspiration except for the incompleteness of his erections.

#### DISCUSSION

In the two cases presented the cause of the priapism was not apparent. In the case of the 40 year old Negro patient there was a previous history of syphilis but neurologic examination did not reveal any evidence of central nervous system involvement although the complement fixation test on the spinal fluid was positive. Most of the reported cases of priapism have been found to be secondary to other disease processes. The treatment of

priapism is far from satisfactory. In cases such as the above, where there is no apparent underlying lesion, it seems likely that the priapism begins as a neurogenic problem. Hyperactivity of the parasympathetic system may account for the development of the erection initially and for sustaining it for an unusual period of time. If this were the only factor, however, spinal anesthesia would be expected to produce prompt remission of the condition. This has not been the case. Thrombosis of the venous channels of the penis following prolonged erection occurs fairly early and probably prevents alleviation by spinal anesthesia. Ansbro and associates<sup>1</sup> reported a case of priapism in a patient who received spinal anesthesia continuously for a 14 day period without relief of erection. Most, if not all, cases of priapism have reached the stage of venous thrombosis before they are seen by the physician. The problem is, therefore, one of treating venous thrombosis rather than parasympathetic hyperactivity.

In 1950, Smith<sup>2</sup> reported the first case of priapism successfully treated by Dicumarol, and in 1955 Fraser<sup>3</sup> reported the second case successfully treated with this drug. This appears to be a rational approach to the disease and probably has its greatest application in the early stages of priapism.

Both heparin and Dicumarol were used in our two patients with out apparent benefit. Price and Penn<sup>4</sup> reviewed a large series of cases in which they used diethylstilbesterol in preventing post operative penile erections. Although it is effective in this situation, it appears to exert no beneficial effect in true priapism.

Various other methods of treating priapism have been advocated, such as division of the pudendal nerves, division of the ischioavernosus muscle, and ligation of the dorsal artery of the penis. They are mentioned only to be condemned and are in general mutilating procedures. Sympathetic block would appear to be the incorrect thing to do, because it would further release the sacral parasympathetic outflow whose action is responsible for erection under normal circumstances.

Evacuation of the corpora cavernosa, either by aspiration or incision and drainage, has been demonstrated to be one of the most effective forms of treatment and has been practiced for over a century. This form of treatment is most efficacious in the early stages of the disease, but in the two cases presented proved beneficial on the 25th and on the 6th day of the disease.

The corpora cavernosa should be thoroughly irrigated with normal saline solution at the time of aspiration to remove clotted blood. A No. 15 or No. 16 gage needle works satisfactorily for this purpose.

Although gangrene is not an infrequent complication of aspiration or incision, according to Bailey,<sup>5</sup> no difficulty was encoun-

tered in the patients seen by the authors. Impotence is a common sequela of priapism. In the one patient who was followed to the present time intercourse was possible although the penis would become only semierect. The other patient was having morning erections when he left the hospital but has been lost to follow up study so his ultimate fate is unknown.

### SUMMARY

Priapism, an uncommon condition, may be caused by central nervous system disorders such as injuries of the cervical cord, syphilis, and multiple sclerosis. It also may develop during such vascular disorders as sickle cell anemia, leukemia, and carcinomatous infiltration of the corpora cavernosa.

The pathogenesis of priapism of unknown cause probably includes initially hyperactivity of the parasympathetic nervous system in most instances. Thrombosis of the venous channels of the penis then maintains the erection and prevents alleviation of the condition by spinal anesthesia.

Evacuation of the corpora cavernosa either by aspiration or incision and drainage is one of the most effective forms of treatment, but is frequently followed by impotence. Anticoagulant therapy is helpful in the early stages of this condition.

The two instances of priapism reported in this article occurred in patients who had no apparent causative disease. The condition was relieved by anticoagulant therapy plus aspiration and irrigation of the corpora cavernosa.

# Spontaneous Rupture of the Stomach in Infants

MARCUS & MOORE Sr., Captain, USAF (MC)

**S**PONTANEOUS rupture of the stomach in the newborn infant is a rare condition Herbut<sup>1</sup> summarized 15 cases with spontaneous ruptures from the English literature in 1943. In one case the perforation was proved not to be secondary to gastric ulceration. He reported an additional case with a congenital defect in the musculature of the stomach wall. Other case reports have been added to make a total of 33 cases recorded in the literature.<sup>2-6</sup> Thirteen of these are described as spontaneous rupture of the stomach not secondary to a gastric ulceration. Pondergruss and Booth<sup>7</sup> in 1946 reported an infant with two perforations of the stomach. In 1947 Burnett and Halpert<sup>8</sup> reported rupture of the stomach in an infant with pyloric atresia. Tudor<sup>9</sup> in 1950 described one case of spontaneous rupture in the greater curvature of the stomach. Eight other cases have been reported between 1951 and 1956.<sup>10-12</sup> This report is of an additional case of spontaneous rupture of the stomach in an infant without gastric ulceration.

Although many theories have been proposed as to the cause of spontaneous rupture of the stomach in infants, the definite cause remains obscure. One author regarded the mechanism of the perforation as a local disturbance in circulation to the stomach wall by embolism, thrombosis, vascular disease, nervous influences, or direct injury to the mucous membrane, with subsequent perforation following the action of the gastric juice. Extensive investigative studies have also been performed to demonstrate an imbalance of pituitary hormones as the cause of the spontaneous gastric ruptures in infants.<sup>12</sup> Congenital defect of the musculature of the stomach wall has been described and considered responsible for the perforation.<sup>1, 7, 9</sup> Tudor and others have reported cases in which no defects in the muscular wall of the stomach could be demonstrated. One patient reported by Ross, Hill, and Haas<sup>10</sup> had a perforation of the stomach with necrosis of the wall, possibly due to intramural hemorrhage.

## CASE REPORT

A five-week old white male infant was rushed in critical condition to the pediatric service of this hospital from a dispensary station of an Air Force base about 50 miles distant on 28 March 1956. Twelve hours prior to admission the infant became acutely ill and had abdominal distention, shallow respirations and cyanosis. He was listless and had an ashen gray color. The infant had a history since birth of periodic episodes of illness characterized with vomiting, hematemesis, melena, poor feeding habits and apparent abdominal pain. He was born after a normal gestation period and an uncomplicated delivery. His mother was a 23 year-old multipara in apparent good health and he had two normal siblings. The infant had been seen at the dispensary station on four previous occasions.

Physical examination on admission revealed a cyanotic infant with a markedly distended abdomen and shallow respirations appearing to be at the very point of death. He responded to immediate emergency therapy of parenteral fluids with electrolytes, antibiotics, hydrocortisone, whole blood and oxygen. Preoperative fluids—approximately 200 ml of normal saline solution in 5 per cent dextrose solution mixed with 60 ml of 1/6 per cent molar lactate containing 100 mg of hydrocortisone and 250 mg of Terramycin (brand of oxytetracycline)—were given intravenously through an emergency venisection and polyethylene tube cannulation of the left ankle. One hundred and fifty milliliters of whole blood was begun as transfusion preoperatively and continued through the surgical procedure. Immediate laboratory studies were made of the patient's blood and urine. Erect and lateral roentgenograms of the abdomen (figs 1 and 2)

Figure 1. Roentgenogram of the abdomen taken in the erect position, demonstrating gas free in the peritoneal cavity under the diaphragm. Figure 2. Roentgenogram taken in the lateral recumbent position, demonstrating pneumoperitoneum.

demonstrated free gas under the diaphragm with a markedly distended gastrointestinal tract. A diagnosis was immediately made of pneumoperitoneum from a ruptured hollow viscus.

February 1977

CASE REPORT—FL 1245 (1)

An emergency operation for intestinal obstruction was performed. The stomach was found to be dilated and the pylorus was closed. The stomach was found to be dilated and the pylorus was closed. The stomach was found to be dilated and the pylorus was closed.

The infant's immediate response to surgery was poor. Therapy included continued gastric decompression and transfusions plus administration of antibiotics. Twelve hours following operation the infant had convulsions, his condition deteriorated and he died on the first postoperative day.

An autopsy performed a total gastrectomy revealed a massive peptic ulcer with all the ulcerated area covered by a thick plastic eschar. The ulcer was not amenable to surgical repair (Fig. 3) was found to be a result of ruptures or obstructive lesions in the duodenum.

Figure 3 Photograph of the stomach after pyloromyotomy. The line in the greater curvature demonstrates the ulcer.

examination of the borders of the rupture demonstrated the mucosa to be hemorrhagic with a moderate amount of acute inflammatory infiltration into the submucosal areas. There was normal development of all layers of the gastric musculature.

Because the generalized peritonitis in this case was due to a rupture of the stomach with profuse spillage of gastric contents all over the peritoneal cavity it was impossible to isolate any one organism as being responsible. It could be classified as a chemical peritonitis.

### DISCUSSION

Although rupture of the stomach in infants is rare prompt treatment can be lifesaving. The importance of making the diagnosis in an infant is considerably greater than in an adult for if left untreated surgically the infant practically always succumbs. Unfortunately the majority of the cases are not recognized clinically in the early stages and usually are diagnosed only after perforation of the stomach or development of peritonitis. Seven of the 33 patients reported have survived operation.

### SUMMARY

Thirty three cases of spontaneous rupture of the stomach in newborn infants have been recorded in the literature. Thirteen infants have been described with ruptures of the stomach not secondary to gastric ulceration. Another case is herein reported of spontaneous rupture of the stomach in a five-week old infant. There are seven surgical survivals reported in infants.

# Kartagener's Syndrome

RICHARD FOULK *Commander MC USN*

**K**ARTAGENER'S syndrome or triad consists of situs inversus, bronchiectasis, and chronic sinusitis. To date, less than 100 cases have been reported in the literature, which indicates the rarity of this condition. The pathogenesis is unknown, but various theories have been proposed. Bergstrom and others<sup>1</sup> stated that the changes noted in the lungs may be a structural defect of the respiratory epithelium causing a predisposition to infection or an altered secretory activity of the bronchial mucous membrane. Olsen,<sup>2</sup> in reviewing the causes of bronchiectasis associated with dextrocardia, agreed that an maldevelopment of the bronchial walls may be the primary factor in the pathogenesis of the bronchiectasis.

At the Mayo Clinic during the period from 1920 to 1941, 85 patients had true dextrocardia with complete transposition of all viscera. Fourteen of these patients had bronchiectasis and 10 of the 14 had diseased sinuses. Adams and Churchill<sup>3</sup> found a 0.03 per cent incidence of this triad in a large hospital. It has been recommended by some authors<sup>4</sup> that all children with dextrocardia and frequent upper respiratory tract infections should have studies to rule out bronchiectasis and sinus infection so that they may be treated early before marked damage has occurred. Antz and others<sup>5</sup> recommended that the families of such patients be screened because there is a familial incidence of this disease. This is noted in the report by Bergstrom and others,<sup>1</sup> in which 2 of 6 siblings had Kartagener's syndrome, 2 had bronchiectasis and sinusitis, and 2 were normal. Two of the five children observed by Dickov<sup>6</sup> were siblings, and all had necrotic tasis accompanying the usual triad.

The treatment is not presently symptomatic and consists of postural drainage, antibiotics as needed, and routine care of sinusitis as required. Depending on the extent of bronchiectasis, lobectomy or segmental resection may at times be indicated.

## CASE REPORT

A 17 year old white woman was admitted to this hospital on 15 August 1955 with a chief complaint of a chronic cough which produced 2 to 3

---

From U S Naval Hospital Memphis Tenn. Comdr Foulk is now assigned to U S Naval Hospital Navy No 3923 FPO San Francisco Calif.

ounces of fetid yellowish green sputum daily. The cough was more severe and productive on arising in the morning and subsided somewhat during the day. She had attacks of wheezing and dyspnea on hot damp days. No history of hemoptysis could be obtained. These symptoms had been present intermittently over the past 12 years. From the ages of 10 to 15 years she had repeated attacks of pneumonia in one or the other of the lower lobes. Frontal headaches had occurred during this same period with an increase in nasal discharge at times. No bloody nasal discharge had been present.

Menarche occurred at 13 years of age and menses had been regular every 30 days lasting five to six days. Her weight had been steady at 110 pounds. In 1954 the patient had an appendectomy at which time the appendix was found to be on the left side. She had pyelonephritis shortly after her marriage in March 1954 and again in August 1955 two weeks prior to admission. The history was otherwise negative except for the common childhood diseases and a chronic blepharitis.

Her mother was living and well. Her father had died at the age of 34 with asthma and bilateral pneumonia. No history of dextrocardia in the father was known. Two brothers and one sister were living and well.

**Physical Examination.** On admission the blood pressure was 105/60 pulse 85 per minute and temperature 98.6 F. A mild blepharitis involved both eyes. The nasal mucous membrane was red and edematous and it was noted that the upper nasal region was widened. The sinuses especially the frontal were visualized with difficulty. Ophthalmoscopic examination was within normal limits. Examination of the lungs revealed crepitant rales in both bases anteriorly and posteriorly which cleared on coughing.

The apex of the heart was found to be in the midclavicular line on the right side of the chest. No abnormalities of the abdomen were noted except that on percussion the liver appeared to be on the left and the spleen on the right. Neither was palpable. The patient's voice was nasal and coarse.

**Laboratory Studies.** A white blood cell count was 10,700 per  $\mu$ l with 65 per cent neutrophils and 35 per cent lymphocytes. Hemoglobin was 12.5 g/100 ml. The urine was normal on examination. Several cultures of the sputum produced no pathogenic bacteria. Roentgenograms of the chest revealed changes in the lower lobes of both lungs which were compatible with bronchiectasis (fig 1). Dextrocardia was present and fluoroscopic examination of the abdomen revealed situs inversus. Bronchoscopic examination revealed diffuse reddening of the trachea and large amount of greenish yellow secretion was noted coming from almost all bronchial orifices and especially from those of the lower lobes. A bronchogram revealed bronchiectasis in the right lower lobe which would be the "right lingula" of the right upper lobe in the left lower lobe and the "left middle lobe" (fig 2). The electrocardiogram was typical of dextrocardia (fig 3). Roentgenograms of the sinuses

revealed a diffuse cloudiness of the ethmoids, antrum, and rudimentary frontal sinuses (fig. 1)

*Figure 1 Roentgenogram of the chest showing dextrocardia.*

**Treatment and Course** The patient was treated with postural drainage for 10 minutes 4 times a day 250 mg of Terramycin (brand of oxytetracycline hydrochloride) every 6 hours Benlyn Expectorant for cough a nutritious diet and other supportive measures. The amount of sputum decreased from two to three ounces daily to approximately one half ounce daily while the patient was on this regimen however, subcrepitant rales were still present in both bases on discharge. She has been followed as an outpatient with very little improvement in her condition. She has not co-operated very well in doing her postural drainage, however no known acute infections have been noted since her discharge from the hospital on 24 August 1955.

## Departments

### A MESSAGE FROM THE A M A

One of the most significant legislative proposals affecting the medical profession in recent years was signed by the President on 7 June 1956, thereby becoming Public Law 569 of the 84th Congress. This law authorizes the Federal Government to assume responsibility for the medical care of dependents of the uniformed services. Because of the law's importance and the many problems it poses for the medical profession, a brief review of the interest and activities of the American Medical Association concerning this subject is being reported this month as a matter of general interest to physicians.

In 1953 the Moulton Commission reported its findings and recommendations with respect to dependent medical care. The A M A opposed the Commission's major recommendations, as well as the subsequent bills which were introduced to implement them. Briefly, the A M A took its position on the grounds that the legislation would result in a big expansion of the military hospital establishment and the continuation of the doctor draft. In December 1954 the House of Delegates of the American Medical Association voted that, "If it is to be the policy of the Government to provide for medical care for dependents of service personnel, the services of civilian physicians and hospitals be used whenever possible, to be paid for at prevailing rates with provision for free choice of physician."

In 1955 Congress shifted its position and developed legislation emphasizing utilization of civilian physicians. In January 1956 witnesses testified on behalf of the American Medical Association before a Subcommittee of the Committee on Armed Services of the House of Representatives. These witnesses urged that if Congress saw fit to provide additional medical care to dependents "increased emphasis should be placed on the utilization of civilian facilities and the services of civilian physicians." It was pointed out, also, that such a program would reduce the requirements of the Armed Forces for physicians and obviate the necessity for any further extension of the "Doctor Draft Law." The Association, recognizing that many problems would necessarily follow the enactment of a program of this type, pledged its support and complete co operation.

---

From the Council on National Defense of the American Medical Association. The views and opinions expressed are not necessarily those of the Department of Defense.  
—Editor

After the bill became law the House of Delegates of the American Medical Association on 11 June 1956 adopted a resolution urging all medical associations to co operate with the Department of Defense "in the provision of medical services to the dependents of servicemen utilizing such insurance, medical service or health plan or plans as encompassed by the law A plan or program for any given geographical area should first be approved by the organized medical profession of that area At the same time the House also directed the Board of Trustees to initiate direct liaison with the Department of Defense and render all reasonable and effective aid and assistance to state and county medical societies toward implementation of the act

Pursuant to this direction the Board of Trustees thereupon appointed a special Task Force on Dependent Medical Care and a series of conferences between this Task Force and the special Task Force of the Department of Defense immediately began to iron out the many problems and issues involved in setting up the program

On 28 29 July 1956 a meeting of representatives of constituent medical associations was called by the A M A at which time the medical care program was discussed At this meeting held in Chicago representatives from the Department of Defense outlined their plans and answered many questions The conference recommended that the constituent medical associations (a) co operate with the Department of Defense in promoting the program (b) determine if they would prepare a schedule of allowances for the reimbursement of physicians for medical services on a state or area basis and (c) indicate preferences for the contracting agent and fiscal administrator

Several meetings were then held by A M A representatives and the uniformed services to consider the nature of the contract between the Government and the contracting agent and fiscal administrator The A M A endeavored to achieve acceptance of a contractual format which would be reasonable and protect the traditional physician patient relationship A M A conferees also sought particularly to maintain local traditions and customs and promote a flexible program that could be activated without creating unnecessary problems Following these meetings draft copies of a contract were prepared and sent to all of the constituent medical societies on 16 October

On 20 October an office in the Main Navy Building at Washington D C was assigned by the Army for use by the American Medical Association For approximately one month during the period of contract negotiations representatives of the Association were available for consultation with representatives of the Armed Forces and the various constituent medical societies Since the June 1956 meeting of the House of Delegates the A M A

Task Force and its special committee have maintained continuous contact with the appropriate committees of the uniformed services in an effort to promote the best possible implementation of the Dependents' Medical Care Act.

In its report to the House of Delegates on 27 November 1956, the Board of Trustees said, "It is obvious that this program through which the Federal Government is purchasing medical and hospital care from private sources for selected dependents of servicemen carries with it some danger to the private practice of medicine. Constant vigilance will be necessary to prevent any significantly adverse effect on the practice of medicine."

At its most recent meeting in Seattle, the House of Delegates recognized the assistance and efforts of the American Medical Association to the Federal governmental agencies and the state medical societies in the negotiations of contracts under the dependent medical care program and urged that this guidance continue in the future, so that problems between the Government and state medical societies may be resolved on an equitable and ethical basis.

The American Medical Association, throughout its dealings with governmental departments and medical societies on this important program, has been guided by the philosophical axiom, "Coming together is a beginning, keeping together is progress, working together is success."

---

## DEATHS

BARHAM Roy Irving, Lieutenant Colonel MSC USA of Los Angeles, Calif. stationed at U S Army Hospital Fort Ord Calif, commissioned a Warrant Officer (junior grade) on 15 December 1942 and Second Lieutenant on 16 May 1943 died 10 December 1956, age 41 at U S Army Hospital Ft Ord of carcinoma of the lung with metastases to brain and liver.

HOLLIS George Beacham Major, MSC USAR of Atlanta Ga. stationed at U S Army Hospital, Fort MacArthur, Calif. commissioned a Second Lieutenant in the Army of the United States and ordered to active duty 25 November 1942 died 13 November 1956, age 44 at U S Army Hospital Fort MacArthur, of coronary occlusion.

ROGERS Owen Edgar Lieutenant junior grade, MSC USAR of New Braunfels Tex. stationed at U S Naval Hospital, Pensacola, Fla. graduated in 1952 from Idaho State College and in 1954 from the University of Utah ordered to active duty 16 August 1954 and commissioned an Ensign 15 December 1954 died 19 November 1956 age 26 at U S Naval Hospital Philadelphia Pa. of acute myelogenous leukemia.

## THE WORLD WIDE ROUNDS OF THE AIR FORCE PHYSICIAN

An oil painting depicting a flight surgeon as he makes his rounds somewhere in the Middle East was presented to Major General Dan C Ogle Surgeon General of the Air Force on 12 December 1956. The painting entitled New Country Doctor Makes World Wide Rounds is one of a series used by Douglas Aircraft Company Inc Santa Monica Calif to stimulate the interest of young people in work being done by members of our armed services.

Left to right General Ogle Major General William H Powell Jr Deputy Surgeon General U S Air Force Mr L E Tollefson, Washington D C representative of the Douglas Company and his assistant Mr S W Cebuhar

The message read in part U S servicemen—in their most remote arctic or tropic outposts—are often closer to medical care than their relatives in isolated areas back home thanks to the work of Air Force aeromedical evacuation units. Trained medical personnel and equipment can be raced by air within hours to almost any spot in the world to treat or evacuate patients.

## NEW AIR FORCE HOSPITAL IN LIBYA

The ever expanding facilities of the Armed Forces overseas were highlighted on 17 November 1956 when the new 7272d U S Air Force Hospital was dedicated at Wheelus Air Base near Tripoli Libya. By good fortune and good timing the dedication ceremony was graced by the presence of a dozen top ranking military and civilian doctors who visited Tripoli on the final leg of a four-week nutrition study through 10 Middle and Near Eastern countries.

Nutrition survey group arrive in Libya for dedication of the new U S Air Force Hospital Wheelus Air Base. From left to right: Colonel Herbert H. Kerr USAF (MC) Major General James O. Gillespie MC USA Dr. Frank B. Berry Rear Admiral Bartholomew W. Hogan Major General Harry G. Armstrong USAF (MC)

Dr. Frank B. Berry, Assistant Secretary of Defense (Health and Medical) headed the group and added one more hospital to the world wide list of dedications in which he has participated as key speaker. He was introduced by Colonel Herbert H. Kerr USAF (MC) Surgeon of the 17th Air Force, who also presented the Honorable John L. Tappin

United States Ambassador to Libya and Major General Harry G. Armstrong, Surgeon General of the United States Air Forces in Europe, Rear Admiral Bartholomew W. Hogan, Surgeon General of the United States Navy, and Major General James O. Gillespie, Chief of Professional Division of the Office of the Surgeon General, Department of the Army, were present along with Dr. Richard A. Kern, Professor of Medicine, Temple University School of Medicine, Dr. Edward D. Churchill, John Homans Professor of Surgery, Harvard Medical School, and prominent members of the Interdepartmental Committee on Nutrition for National Defense.

The Honorable John L. Tappin, Ambassador from the United States to the Kingdom of Libya, speaking at the dedication of the new 150-bed U.S. Air Force Hospital at Wheelus Air Base, Tripoli, Libya.

The new hospital is a 150-bed one-story structure adapted from standard plans developed in the Department of Defense. It is completely air conditioned and offers virtually all the latest diagnostic and treatment facilities. When fully staffed and tied in with a wide spread air evacuation system, it will serve members of the U.S. Armed Forces and their families from Morocco to the Burma border. Wheelus Air Base itself is the Headquarters of the 17th Air Force, which is charged with complete logistic support for this vast area. Comprehensive medical service is a major part of this mission.

# OFFICERS CERTIFIED BY SPECIALTY BOARDS

## Supplementary Listing

According to information from the Office of the Surgeon General, U S Air Force, the following regular Medical Corps Officers have been certified by the boards indicated since the listings published in previous issues of this *Journal*

### American Board of Pediatrics

### Board of Thoracic Surgery

(A Subsidiary Board of the American Board of Surgery)

Frederic E. Foley Lt Col USAF

Certificates in Occupational Medicine are available at present and will be published in a later issue

### THE NPN TEST

No laboratory procedure should ever be considered as a routine measure. A nonprotein N or blood urea N test should be made on the blood of any patient who has albumin in his urine, progressive hypertension, evidence of arterial damage in his eyegrounds, or in any case of definitely enlarged prostate. Otherwise this test should be done only when there is a definite indication that it might be of value in the patient's illness. In health examinations at yearly intervals it may be done on the first examination, not repeated unless for definite reason.

—JAMES M. NORTINGTON, M.D.  
in *Clinical Medicine*  
p. 11 Jan 1955

## MILITARY MEDICO-DENTAL SYMPOSIUM

The Fifth Annual Military Medico Dental Symposium under the auspices of the Commandant, First Naval District, will be held at the U S Naval Hospital, Chelsea Mass, and civilian institutions in Boston, Mass 20 to 22 March 1957. The three-day program will have as its theme "The World-Wide Significance of the Preventive Aspects of Military Medicine and Dentistry."

The meeting on the first day will be conducted at the U S Naval Hospital. The second day, a tour of the School of Public Health of Harvard University will be conducted by Doctor John C Snyder, Dean of the School, following which lectures will be given at the Jimmy Fund Auditorium. Lectures on the third day will be held at the Jimmy Fund Building, the Joslin Auditorium at the New England Deaconess Hospital, and the U S Naval Hospital.

Among the prominent guests and speakers on the opening day will be the Honorable Frank B Berry Assistant Secretary of Defense (Health and Medical), Rear Admiral Bartholomew W Hogan Surgeon General of the U S Navy, Major General Silas B Hays, Surgeon General of the U S Army, Doctor Howard Root President Massachusetts Medical Society, Captain Shields Warren, MC USNR Professor of Pathology Harvard Medical School, Doctor Chester S Keefe Director, Boston University School of Medicine, and Agnes Ohlson R N, President American Nurses' Association. Captain R Cannon Eley, MC, USNR Chief of Isolation Service Children's Hospital, and Assistant Clinical Professor of Pediatrics, Harvard Medical School, is serving as general chairman of the Symposium.

The Symposium has been approved for retirement point credit for those in attendance who are on the Active Status List in the Armed Services Reserve program, provided they register with the authorized military representative assigned the duty of recording daily attendance. Programs and additional information may be obtained by writing to the District Medical Officer First Naval District, 495 Summer Street, Boston 10 Mass.

## MEDICAL OFFICER ELECTED PRESIDENT OF BOARD OF PSYCHIATRY AND NEUROLOGY

Captain George Neely Raines MC USA was elected President of the American Board of Psychiatry and Neurology during the annual meeting of the Board in New York 9 to 11 December 1956 Captain Raines is the first military medical officer on active duty to be elected to this position He served as a Director of the Board since 1949 and was its Vice President last year

Captain Raines is on duty at the Bureau of Medicine and Surgery Washington D C as Head of the Neuropsychiatry Branch and is Professor and Director of the Department of Psychiatry at Georgetown University School of Medicine

## Reviews of Recent Books

THE PRACTICE OF MEDICINE edited by Jonathan Campbell Meakins C B E M D, LL D D Sc 6th edition 1916 pages 318 illustrations including 4 in color The C V Mosby Co St Louis Mo, 1956. Price \$16

This sixth edition of Meakins' *Practice of Medicine* bears little resemblance to the preceding five editions. Whereas this book was previously produced by Dr Meakins with a few chapters credited to four or five of his colleagues the current volume represents a coordinated effort by 24 associate editors and 87 contributors from medical educational and research centers in 21 states and the District of Columbia in addition to Montreal, Canada, and Cardiff Wales.

The 214 chapters are organized into 22 sections, four of which pertain to specific infections due to bacteria, viruses, spirochetes, and rickettsiae. Included also are the chemotherapy of infection, the allergic states and diseases due to abnormal environment, and a final section on the psychosomatic aspects of medicine. Most sections are preceded by an introduction containing general facts and principles pertaining to all diseases in that group. Several sections (notably those on cardiovascular, renal, pulmonary and hepatic diseases) devote considerable space to basic physiologic, chemical and anatomic considerations that greatly enhance an understanding of the section as a whole.

Although the number of pages has been increased from 1558 to 1916 and illustrations reduced from 518 to 318 the presentation of many subjects is quite brief. This is no reflection on the quality of the book but rather an indication of the great advances which have been made in our knowledge of medicine and the difficulty which coverage in a single volume entails. The greatest space is generally allocated to conditions of greatest frequency and importance. The illustrations included are excellent, the text is clear and readable and the references though restricted in number, are well chosen. This book is recommended as a valuable addition to the armamentarium of medical students, general practitioners and internists alike. —ALBERT A BIEDERMAN, *Col. W. C. C.*

ANGIOCARDIOGRAPHIC INTERPRETATION IN CO GE'ITAL EASE by Herbert L. Abrams, M D and Henry S. J. L. M. D. Monograph in The Bannerstone Division of American Lectures in Pediatrics edited by John A. Anderson M D 233 pages 1956. Price \$11. Thomas Publisher Springfield, Ill 1956. Price \$11.

This publication is an excellent monograph in The Bannerstone Division of American Lectures in Pediatrics. The case reports are from a series of over 350 angiocardio-graphic studies.

congenital heart disease most of which examinations were performed in children under the age of three

Part 1 summarizes the historical background of angiocardiology the techniques contrast media and roentgen equipment employed reactions to angiocardiology general principles of interpretation and the role of aortography in diagnosis Part 2 is divided into 27 sections each dealing with one or more specific congenital anomalies These sections stress particularly the interpretation of the differential diagnostic features apparent in contrast roentgen studies No attempt was made to describe in detail the clinical physiologic pathologic and surgical data except insofar as seemed necessary to clarify the angiocardio-graphic anatomy

In each section variable emphasis is given to electrocardiographic and roentgenographic characteristics in addition to either angiocardio-graphic or aortographic findings The book is profusely and adequately illustrated with excellent reproductions of angiocardio-graphs which are accompanied in each instance by labeled easy-to-read diagrammatic sketches In the appendix there is a short useful three-page reference table of differential diagnosis

The authors have been unusually successful in their efforts to bring into focus the role of angiocardiology in congenital heart disease They have accurately described and portrayed the diagnostic patterns which have merged up to this time in the summary of their and others' experiences in evaluating the usefulness of contrast roentgen studies in congenital heart disease This book is highly recommended for inclusion in the library of all physicians interested in the diagnostic evaluation of congenital cardiovascular anomalies —GEORGE C. BESS Col USAF (MC)

**TREATMENT OF THE CHILD IN EMOTIONAL CONFLICT** by Hyman S Lippman M D 298 pages The Blakiston Div. McGraw-Hill Book Co Inc New York N Y 1956. Price \$6.

Dr Lippman has drawn upon more than 25 years of experience with disturbed children to write a book which will be of interest primarily to psychoanalytically oriented therapists However portions of his book may be recommended to a much broader audience

In the section devoted to "approaching therapy" Lippman briefly describes the division of therapeutic labor among the members of the "psychiatric team" in a child guidance clinic He gives a simple straightforward exposition of the necessity for eliciting the co-operation of the family of the "emotionally conflicted" child in order to guarantee maximum effectiveness of therapy and minimum anxiety for the child Pediatricians teachers personnel of juvenile courts welfare agencies and others whose duties require them to initiate or advise on referrals of children to guidance clinics will find this discussion of significant interest

The second major portion of this book details a broad array of mental and emotional disturbances in children with the primary emphasis

given to the treatment of the various well chosen cases described. In addition, a brief, annotated bibliography devoted specifically to "the psychotic child" will be welcomed by readers especially interested in that subject. The chapters on "the psychopath" and "the neurotic delinquent" were especially impressive because of the author's manifest patience and optimism in approaching these vexing cases.

However, the reader who does not share Lippman's Freudian orientation will probably object strenuously to his apparently uncritical deification of the id-ego-superego trichotomy as though it were *factual* rather than *conceptual*. The book might have been greatly improved by occasional references to alternative and, at least, equally plausible explanations of the dynamics of the various emotional disturbances discussed.

The final portion of the book deals briefly with the problem of prevention and some principles of therapy, the latter section being somewhat hortatory, but justifiably and acceptably so.

One wishes that specific attention had been devoted to the widespread existing mental health education and information programs. Many of these programs involving substantial investments, are devoted to fostering secure, healthful relationships within the family which Lippman describes as "the most valuable unit in any program for preventing emotional conflict in children."—NORMAN A. HILMAR Capt. MSC USA

**UROLOGICAL SURGERY**, by Austin Ingram Dodson M. D. F. A. C. S. with nine contributors. 3d edition. 868 pages. 664 illustrations. The C. V. Mosby Co. St. Louis Mo. 1956. Price \$20.

The third edition of this book maintains the high standards set by the first two editions. In keeping with the rapid advances in urologic surgery, new and in general excellent material has been added on post-operative urinary incontinence, neurologic uropathy, stress incontinence in the female, and perineal prostatectomy. The chapter on the adrenal glands has been revised, as has the section on uretero-intestinal anastomosis. To make room for these revisions, certain chapters appearing in the second edition have been deleted without materially detracting from the overall value of the book. These include the chapters on radiation therapy, acid base balance, and blood transfusions. The latter two are included more appropriately in a section on pre- and post-operative care.

Although the book reflects a genuine attempt to maintain a degree of completeness and up-to-dateness which is all too often lacking in works of this type, criticism might be levied at the omission of a description of the transthoracic approach to the kidney, a procedure which would seem to be definitely entrenched in the surgical armamentarium, and of the use of isolated segments of small and large intestine as urinary conduits. The latter procedure, although admittedly a rather recent innovation, seems deserving of more than one or two sentences. The section on ureterocystostomy is excellent, but the procedure is not included. On page 61 appears the

presacral oxygen insufflation air embolism is almost unknown This is misleading The statement on page 731 that very little if any pathologic change takes place in the undescended testicle before puberty will certainly find dissenters

Minor criticisms notwithstanding this book is the most outstanding treatise on the subject in the English language The printing paper and illustrations are excellent and this volume should find a place of distinction on the bookshelves of all those engaged in surgery of the urinary tract and male reproductive system

—HOWARD POLLACK Capt USAF (MC)

Proceedings of the Round Table on LYSERGIC ACID DIETHYLAMIDE AND Mescaline in Experimental Psychiatry Held at the Annual Meeting of the American Psychiatric Association Atlantic City N J May 12 1955 Edited by Louis Cholden M D Chairman 85 pages illustrated Grune & Stratton Inc New York N Y 1956 Price \$3

This 81 page monograph reports the panel discussions held on this subject at the 1955 Annual Meeting of the American Psychiatric Association The participants represent some of the most fertile and imaginative research minds in the field of American and European psychiatry Also included are the stimulating comments on mescaline effects by that erudite man of letters Aldous Huxley The focal point is the production of an artificial psychosis by means of LSD 25 The means by which such minute doses of this drug produces symptoms is discussed and it is concluded that the resulting mental dysequilibrium is not simply due to its serotonin inhibitory properties but may be mediated by enzymatic processes

Dr Paul Hoch contributes stimulating practical comments on the tranquilizing drugs which with Sodium Amytal and Pervitin seem to afford symptomatic relief of the artificial psychoses induced by LSD This leads to Max Rinkel's scholarly comments on the various chemical theories of the causes of schizophrenia and the possible roles of adrenalin metabolites especially adrenochrome and adrenoxin Adrenochrome is described as the first substance thought to occur (naturally) in the body which has been shown to be a hallucinogen Disturbances in the adrenalin cycle seem theoretically plausible especially in view of the similar mechanisms found in phenyl pyruvic acid oligophrenia tyrosinosis alkaptonuria and albinism The clinical uses of LSD are discussed from the treatment viewpoint by Dr Sandison and Dr Charles Savage for neurotic and psychotic patients

This is a stimulating volume and should interest all clinical psychiatrists who desire to keep abreast of the current biologic theories of schizophrenia It offers some rational basis for the effects of the now popular ataractic drugs in emotional disorders Dr Louis Cholden has done a signal service to researchers and clinicians in this field by his expert compilation and judicious editing and those who knew him will be saddened by his untimely accidental death only a few months after he completed this monograph

—JOHN P McMULLIN Capt MC USN

**THE NATURE OF BRUCELLOSIS** by Wesley W. Spink M D D Sc 464 pages illustrated The University of Minnesota Press Minneapolis Minn, 1956

This book was engendered by a decision made in 1945 to study critically 100 bacteriologically proved cases of brucellosis and to follow the subsequent course of the patients

After giving credit to many colleagues at the University of Minnesota and abroad the author discusses all of the aspects of brucellosis of interest to physicians Besides devoting chapters to the clinical features, he discusses historical epidemiologic, bacteriologic, and other aspects Pathogenesis and pathology are well described without excessive devotion to details of interest only to pathologists

The author's great personal experience with brucellosis together with his opportunities for observation in foreign countries and his knowledge of the vast medical literature, qualify him uniquely as an authority on brucellosis His style is clear and although there is a slight amount of repetition there is little redundant material

Three appendixes giving reports of the U S Livestock Sanitary Association seemed unnecessary but in general the book's contents are germane and logically presented —ROBERT J HOAGLAND Col MC USA

**ENDOGENOUS UVEITIS** by Alan C. Woods M D, with illustrations by Annette Smith Burgess 303 pages illustrated The Williams & Wilkins Co, Baltimore, Md, 1956 Price \$12.50

The material of this book is presented under the headings of the different phases of the uveitis problem—classification pathogenesis pathology, diagnosis and treatment—rather than as consecutive discussions of each individual clinical entity since this is the sequence in which the problems of uveitis confront the student

Methods used in diagnosis and treatment are described in detail the illustrations are excellent, and the bibliography is adequate This book is the most complete treatise in print today on endogenous uveitis and fills a real need of all practicing ophthalmologists The section on the office management will be of inestimable value to the busy practitioner The phenomenal growth in knowledge about uveitis will make this book a standard reference in all ophthalmic libraries

—KENNETH HUDSON Lt Col MC USA

**HUMAN OVULATION AND FERTILITY** by Edmond J Farris Ph D 159 pages illustrated J B Lippincott Co Philadelphia Pa, 1956 Price \$6.50

This text sets forth the record of years of hard, tedious careful investigations regarding ovulation time in the human menstrual cycle A new and apparently very accurate, simple test for determination of this exact date is outlined in clear practical terms Tables of results in actual fertility problems of patients who have successfully conceived healthy children are offered Methods of study of barren couples, legal aspects of artificial insemination, and use of irradiation in an eff

stimulate ovulation are all discussed quite clearly in this text. Many facts of this intricate problem are discussed freely.

This concise and authoritative text will be of value to specialists and general practitioners alike. Here is a practical method for calculating fertile days with greater accuracy than those used heretofore. The fine chapter "Information of Value to the Barren Couple" will be of great aid to the physician in counseling his infertile patients.

This book is carefully documented and well worth careful study by all physicians interested in gynecology and obstetrics.

—ROY W TANDY Sr Capt MC USN

**BIOCHEMISTRY OF THE EYE** by Antoinette Pirie M A Ph D and Ruth Van Heyningen M A D Phil 323 pages illustrated Charles C Thomas Publisher Springfield Ill 1956 Price \$7

This rather technical book presents a well documented compilation of what is known of the detailed chemistry of the major portions of the eye. As the authors state in their preface they have avoided details of subjects on which vast amounts of literature have already appeared likewise they have avoided areas in which little of the biochemistry is authoritatively known such as tears lids lacrimal glands conjunctiva sclera choroid or optic nerve. Of the remaining functions of the eye almost one half the space is allotted to the lens and its chemistry. Facts are stated and credits are given without a great deal of discussion. The authors fail to indicate how much of the reported work is their own. The extent of their contributions is reflected in the long list of references at the end of each chapter. Their modesty is commendable.

Lesser but adequate space is devoted to the biochemistry of the cornea the retina the vitreous and the relationship between the aqueous humor and the ciliary body. A final chapter deals briefly with the tremendous subject of the effects of nutritional disease upon the eye.

That the book is intended for all physicians as well as ophthalmologists is evident. A glossary carefully defines cataract macula and a host of other obvious words. This however does not detract from the book. The manner in which this highly technical data is presented is most pleasing. In particular I enjoyed the too brief chapter on chemical aspects of vision. The subject matter of the whole book was easy to follow not technical beyond reason and methodically presented. It is worth the time of everyone interested in ophthalmology.

—DAWSON A. MILLS Capt MC USN

**PLASTIC REPAIR OF GENITO-URINARY DEFECTS** by George Bankoff M D D Ch 355 pages illustrated Philosophical Library Inc New York N Y 1956 Price \$1 50

The title of this book is not descriptive of its contents as the defects and anomalies of neither kidney nor ureter are considered and surgical corrections of some diseases of the lower tract (e g impotence testicular tumors) are included.

The book is predicated on an excellent idea—the need of a handbook outlining genitourinary defects, accompanied by a collection of the various successful surgical techniques employed to correct them. However, authorship in a specialty field requires considerable technical experience in all areas covered or collaboration with an expert in certain areas. The author, a plastic surgeon, apparently did not seek the collaboration of a urologist. The book would be strengthened by deletion of the redundant outline of basic anatomy and by omission of the section on sterility and impotence since the latter is not pertinent to the title.

The section on malformations and plastic repairs is a fair summary of the many and better known surgical techniques described in correction of genital and lower tract urologic defects and anomalies. The illustrations and reproductions range from fair to good, but the accompanying text often lacks clarity or correlation with the pictures which they

This book published in 1956 is based on a bibliography on literature prior to 1948. Widening of horizons in plastic surgery since the advent of chemotherapy with abolition of tuberculous abscesses with a streptomycin sulfate and modification of anastomosis and tissue techniques has occurred in the interval. The necessity of editing and proofreading, especially by a urologist, is obvious when one finds the Tork technique for rectopexy repeated several pages later under "cysto-orchidectomy."

—CHARLES W. HOFFMAN, Jr., LL. CO. M. 1954

**ESSENTIALS OF PSYCHOLOGY** by Werner Wolff, 2d revised and enlarged edition of *Wolff's Psychology* 385 pages, illustrated, Grune & Stern, Inc., New York N. Y. 1956. Price \$6.50.

This volume is divided into 10 chapters covering the field of psychology, the areas of research, and the chief problems being dealt with by present-day workers in the field. Topics such as perception, retention, thinking, intelligence, emotion, personality, attitudes, and motivation are reviewed, their meaning in the study of man discussed, and the pertinent literature brought to the attention of the reader.

The volume provides an excellent analysis and synthesis of the problems facing psychology as a science compared to the problems facing the other sciences. However, the author's attempt to compress the field of psychology and pertinent research into an introductory volume has resulted in a vocabulary difficult for a beginning student.

The effort to present these studies within the framework of the developing science of psychology is skillful. The difficulties arising in psychology when the methods and restrictions of other sciences are foisted upon the studies of human behavior are discussed and well exemplified. Many highly considered theories are brought to the reader's attention by the author, and the evidence garnered as to the correctness of these theories is succinctly discussed. The book on the whole is interesting and useful for the serious young student of psychology who needs a general view of the field. —PHILIP L. GOLDBERG, CAP. USAF (MSc)

**ATLAS OF EXFOLIATIVE CYTOLOGY** by George N Papanicolaou M D Ph D 230 pages of text 26 full page color plates complete with loose-leaf leather binder Published for the Commonwealth Fund by Harvard University Press Cambridge Mass 1954 Price \$18 Supplement I for insertion in 1954 Atlas 50 pages of text 17 full page color plates Published for the Commonwealth Fund by Harvard University Press Cambridge Mass 1956 Price \$4

This important atlas of exfoliative cytology profusely illustrates normal and neoplastic cells from various secretory and excretory fluids of the body. It is in loose leaf form which allows periodically the addition of new plates as they are published in this rapidly growing field.

It is a truly comprehensive approach to the study of cells exfoliated from the respiratory digestive urinary and male and female genital systems pleural peritoneal and hydrocele fluids breast secretions and aspirations and changes noted in cells from various metabolic and hormonal influences. The latter is illustrated for example by plates of normal and abnormal mitotic figures and cells from vaginal cervical and urine sediment smears in cases of pregnancy.

In Supplement I the plates show a comparative illustration of cells as seen in tissue sections and in smears. This brings out clearly not only similarities but also marked dissimilarities between the cells in the two different preparations.

Another useful feature of the atlas is a description of the technical procedures used in obtaining and preparing smears from various sources. This will make the book valuable to the clinician as well as to the pathologist. —VERNOE MARTENS Capt MC USA

**PROCTOLOGY** by Harry F Bacon M O Sc D LL D Stuart T Ross M D and Porft to Mayo Recto M D M Sc 441 pag 228 illustrations and 5 plates in full color J B Lippincott Co Philadelphia Pa 1956 Price \$10

This concise almost outline type book is in reality a rewritten version of *Essentials of Proctology* by the senior author originally published in 1943. The present authors have very carefully eliminated extensive and controversial material relating to etiology history pathology anatomy treatment et cetera. In fact no bibliography or reference to other authors is included. It is designed to be a quick reference book primarily for medical students interns general practitioners and busy practicing surgeons. To this end the authors succinctly accomplish their purpose in delineating the fundamentals of basic proctology.

Briefly the essential anatomy and physiology are taken up special examination procedures and laboratory tests are described while anesthetic agents pre and post operative treatment and special nursing care are covered. The regional disease processes and their surgical treatment in both office and hospital are then described by chapters.

each factual, definite and to the point. A special chapter on intestinal parasites by Samuel W. Eisenberg of the Department of Proctology at Temple University has been added, and although far from being all inclusive does cover the more commonly encountered parasites.

The authors are to be congratulated on setting down in such a clear intelligent manner their extensive experience in the field of proctology.

—LISTER J. POPE Capt MC USN

**CLINICAL ORTHOPAEDICS** No. 7 "Tumors of Bone" *Anthony F. De Palma* Editor-in-Chief. This number contains a special third section on "Motorist Injuries and Motorist Safety" by *Jacob Kulowski MD*. 354 pages illustrated. J. B. Lippincott Co. Philadelphia Pa. 1956. Price \$7.50.

Anthony F. De Palma shows an unusual flair in assembling contributions outstanding both in scientific value and in reader interest.

The section on bone tumors includes essays by the world's leading authorities on the subject such as Geschickter, Copeland, Jaffe, Stein and others. While the material presented is not new, the presentations are concise, authoritative, well illustrated and backed by survival statistics.

The section devoted to general orthopedics is composed of eight contributions. The general trend of this section is bolder, more experimental than the more orthodox attitude toward treatment of the bone tumors. Outstanding research reports are Cobey's search for nonallergic polymetizing plastic and Tucker's use of cultured calf bone in human bone grafts. Of clinical interest is a treatise from the Albert Einstein Medical Center on calcification of the intervertebral disk disappearing dormant and silent.

The section on motorist injuries and safety is encouraging as it reflects the serious and systematic efforts of a team including physicians, statisticians and engineers to find solutions to present problems and those in the future. The subject treatment is both thorough and concise. The bibliographies after each of the 18 separate chapters are exhaustive.

—FRANK DEHNE Col MC USA

**MUSCLE TESTING** *Techniques of Manual Examination* by *Lucille Daniels M.A.* *Marian Williams Ph.D.* and *Catherine Worthingham Ph.D.* 2d edition. 176 pages illustrated. Format and text illustrations by *Harold Black*. Anatomical drawings by *Lorene Sigal*. W. B. Saunders Co. Philadelphia Pa. 1956.

I have used the first edition of this book for many years and considered it to be the best text on the subject. However, I believe the second edition surpasses the 1946 one in many instances.

The material is presented simply and is readily understandable. The illustrations are most effective. "Positioning of a patient" gives the student an excellent illustration and guide of the proper way to position a patient. Also in many illustrations throughout the book the patient is pictured with more support which is much less startling to the patient.

therefore he is less apprehensive of trying to perform the desired exercise procedure

The authors have added considerable valuable information to this manual. The facial muscles are excellently outlined. This feature was not available in the 1946 edition and is especially helpful to both the student and the physical therapist.

This manual is written in a clear easy to read style. I highly recommend this text for teaching muscle testing and also feel that it would be an excellent reference source for all physical therapists.

—MAURINE MECKES Lt MC USN

**THE SPINE** Anatomico-Radiographic Studies Development and the Cervical Region by Lee A Hadley M D 156 pages illustrated Charles C Thomas Publisher Springfield Ill 1956. Price \$6.50

This book is a well written monograph discussing the embryologic development of the spine various developmental disturbances that produce anomalies certain conditions such as trauma and disease that cause abnormal anatomical variations and the effects of disk degeneration. It deals primarily with the cervical spine with special reference to the differentiation between anomalies and the results produced by injuries and the medicolegal implications thereof. Only brief mention is made of conditions found in the other regions of the spine. The text is concise and amply illustrated with well chosen good quality roentgenograms micrograms and photographs of living and cadaver specimens. It should prove of interest to the roentgenologist orthopedist and neurosurgeon. —MALCOLM W MASON Capt MC USN

**PHARMACOLOGY AND ORAL THERAPEUTICS** A Textbook for students and Practitioners by Edward C Dobbs D D S F A C D 11th edition 579 pages illustrated The C V Mosby Co St Louis Mo 1956 Price \$9

This is the 11th edition of a widely known text by an outstanding authority in the field of pharmacology. The introduction of many new drugs with the resultant improvement in therapy has prompted the preparation of this new and latest edition. The title has been changed to emphasize the field of oral medicine and the drugs are described to conform to the current revisions of the 15th edition of the U S Pharmacopoeia and the 10th edition of the National Formulary.

The text has been divided into two distinct categories. Pharmacology and therapeutics. In the first part the drugs have been grouped into chapters representing anatomic and physiologic systems with a concise description of the anatomy and physiology of the system under consideration. The drugs are then described and correlated in accordance with their clinical indications and dosage. This section includes a rather detailed description of the types and pharmacology of various local anesthetics.

Part 2 is prefaced with an excellent chapter on prescription writing, rewritten to conform to the new nomenclature of the U. S. Pharmacopoeia and the National Formulary. The remainder is devoted to the treatment of the more common diseases encountered in the field of oral medicine. While the book is not a complete coverage of diagnoses and treatment planning, it is lucid, concise, and accompanied by excellent tables and prescriptions.

This volume should be used by the general practitioner as a reference or course in pharmacology and oral therapeutics and as a daily source of information in the use of new drugs and their therapeutic indication.

—JOHN R. McFLOY 1st Col. USAF (DC)

**VENOUS RETURN** by Gerhard A. Brecher M.D. Ph.D. 148 pages illustrated. Grune & Stratton Inc., New York N.Y., 1956. Price \$6.75.

This monograph presents a comprehensive account of Dr. Brecher's work and is an excellent historical survey of efforts preceding his own. The illustrations are profuse and excellent and many are original. The author has applied synthetic and analytic approaches to the problem of venous return. This monograph is the only current one that gives a comprehensive analysis of the determination of venous return and its adaptation to cardiac output based on experimental measurements. It is excellent background material for surgeons and radiologists alike, particularly those doing thoracic or cardiac work. The author accomplishes this work by using completely modern equipment in testing his concepts. His final remarks are worth repeating: "The combination and integrated action of all factors—the ventricular injection, the respiratory pump, the systolic ventricular attraction, the recently demonstrated diastolic ventricular suction, the muscle pump and veno motor activity—widen the margin of safety which assures the adequacy of venous return under normal and abnormal conditions."

—ARCHIBALD G. M. MARTIN III Maj. USAF (MC)

**STUDIES IN TOPECTOMY** edited by Nolan D. C. Lewis M.D. Carney Landis Ph.D. D.Sc. and H. E. King Ph.D. 248 pages. Grune & Stratton Inc. New York N.Y., 1956. Price \$6.75.

This monograph describes a series of studies done by the New York State Associates in Brain Research between June 1948 and April 1949. The general aim of the project "was the furtherance of the scientific evaluation of psychosurgery as a therapy together with the accumulation in passing of whatever basic information might be gathered concerning the interrelation of frontal lobe brain structure and human behavior." Some 95 patients with various types of schizophrenic reactions were used for the study, 66 of these patients had one of two types of topectomy performed and the remainder (29) served as controls.

The discussion of this complex subject includes the surgical procedure, physiological effects, vestibular function, autokinesis, psychometric studies, complex mental functions, a time sampling study of

activity psychophysiology sexual behavior two independent evaluations of psychiatric effects and social service studies In short under one cover is presented a host of multidisciplinary reports concerned with the same patient group Each discipline presents a more or less self contained report concerning the specific questions raised by the psychosurgical procedure The chapters are clearly and excellently written with adequate bibliographic material and the volume has a better than average index which makes possible excellent cross reference between the disciplines concerned

—SAMUEL V THOMPSON Capt MC USN

**INTERNAL MEDICINE** *A Physiologic and Clinical Approach to Disease* by Robert P McCombs M D F A C P 706 pages illustrated The Year Book Publishers Inc Chicago Ill 1956 Price \$10

This volume which is handbook size comprises a summary of the most important clinical facts physiologic concepts diagnostic methods and therapeutic measures used in the study and management of internal diseases The author states in the preface that the handbook size has been retained by avoiding duplication and eliminating detailed discussions of subjects that are primarily related to independent specialties His aim is attained and a very complete table of contents reference bibliography for each chapter and index with cross reference make the handbook readily usable in daily work

The book is a useful handy and ready reference for the specialist in internal medicine and a valuable addition to the library of any practicing physician —WILLIAM S GEORGE Col MC USA (Ret)

**NEW BASES OF ELECTROCARDIOGRAPHY** by Demetrio Sodi Pallares M D with the collaboration of Royall M Calder M D 727 pages 520 illustrations The C V Mosby Co St Louis Mo 1956 Price \$18 50

This is the English translation of the third Spanish edition of Dr Sodi Pallares text It brings together in one volume the author's views on many of the controversial principles of electrocardiography and summarizes the extensive experimental and clinical studies that have been conducted by the author and his associates

The mathematical and electrical basic principles of electrocardiography are discussed in considerable detail as well as the experimental methods from which his conclusions are derived One of the most valuable sections of the text for the clinical cardiologist is a summary of the careful correlative studies that have been accomplished relating electrocardiographic change and anatomic diagnosis in congenital heart disease The author emphasizes the value of these changes in the differential diagnosis of congenital heart disease Often they reflect the hemodynamic alterations more accurately than do the clinical and radiologic features This is a complex technical work that is not designed to teach clinical electrocardiography to the average clinician However it is highly recommended as a valuable reference work for the investigator or advanced student of electrocardiography

—SELDON J WALKER Col MC USA

**ESSENTIAL UROLOGY**, by Fletcher H. Colby M. D. 3d edition (26 pages illustrated) Williams & Wilkins Co. Baltimore, Md., 1946. Price \$8

Attesting to the popularity of this book is the fact that this is the third edition to appear in the last six years. An attempt has been made to keep pace with the rapid advances in the field of urology. To a large extent this has been very successful although retrospective pro-nomography is not discussed. There have been clarifying revisions in the field of urinary tract infections, including tuberculosis. As in the previous editions the sections on anatomy and physiology are especially well done. The entire field of urology is covered in this book which of course limits the exhaustiveness with which each entity can be covered. While the detail desired by the specialist is not to be found the list of references is excellent. This makes the book of value to the specialist as well as to the student, intern, resident, and teacher.

The section on basic sciences as related to urology could be read with profit by all those preparing for their board examinations in urology. This is probably the best small book on urology in the English language. — HOWARD POLLACK, Capt. USAF (MC)

**DERMATOLOGY** by Donald M. Pillsbury M. A. D. Sc. (Hon.) M. D. Walter H. Shelley M. D. Ph. D. and Albert M. Aligman, M. D. 1st Ed. 1,330 pages 117 illustrations on 364 figures. W. B. Saunders Co. Philadelphia, Pa. 1956. Price \$20

This integrated effort of three well known dermatologists with varied and extensive experience in teaching, research, and clinical practice is novel and rewarding through its reflection of the combined years of experience represented. The result is not only an informative and useful text but one with information which is conveniently accessible.

In addition to a lucid and titillating preface (worth the reading) there are 13 chapters on applied basic principles of which the chapters on mycology and bacteriology of the skin are unique to this book. Another five chapters discuss allergy and hypersensitivity, four chapters are devoted solely to diagnosis, while three chapters are concerned with a discussion of therapy. This portion of the volume represents about 30 per cent of the work; the balance, or remaining 27 chapters, deals with cutaneous medicine (clinical dermatology). Throughout the role of the skin as it reflects systemic disease is stressed, making the book of particular value to all practicing physicians as well as invaluable to the internist.

The discussion of principles of diagnosis constitutes an excellent exposition of differential diagnosis. The accompanying photographs admirably illustrate the differentiation necessary to make a diagnosis. The clinical section, more than conventional, includes all fresh and new material with the chapter on dermatitis and eczema practically a classic. The discussion on therapy is outstanding in its clear cut and no-nonsense evaluation, particularly in its account of adrenocortical preparations. The chapter on ionizing radiation is the first practical account

that I have run across. Its conservatism is laudable and the content completely adequate. The index of 48 pages is complete yet not redundant.

The authors have indeed achieved their purpose in presenting dermatology in a new and readily acceptable form free from obvious error or major controversy. Simplified yet with full coverage, scholarly but not pedantic. Its boldness in deviating from past patterns makes it enjoyable to read and convenient as a ready reference.

—ROBERT L. GILMAN Capt MC USN

THE LABYRINTH Physiology and Functional Tests by Joseph J. Fischer  
M D 206 pages illustrated Grune & Stratton Inc New York N Y  
1956 Price \$6

This book fulfills a need which has been very evident for a long time. It is an eminently successful attempt on the part of the author to bring organization out of chaos. The literature is replete with articles pertaining to theories, hypotheses, and clinical aspects of function of the labyrinth. The author states concisely the controversial theories and follows with clinical application of labyrinthine functions.

The complex subject of otoneurology and its numerous facets are dealt with in terms which are easily followed and understood. This material is concisely and accurately presented. The bibliography is voluminous and material well indexed for ready reference. This is an excellent book which is especially designed for the resident in otolaryngology as well as the neurologist.

—FRANK J. SHAFFER Col MC USA

DISEASES OF THE BREAST by C. D. Haagensen, M D 750 pages illustrated  
with 404 figures and 25 charts W. B. Saunders Co Philadelphia Pa  
1956. Price \$16

The author is to be commended on a very readable and comprehensive text. Every conceivable aspect of disease of the breast appears to have been covered.

Worthy of special comment is the section on anatomy. Also the surgical treatment of carcinoma of the breast is given careful treatment. The author's technique is clearly described in detail and well illustrated. In addition, the McWhirtet method of simple mastectomy and the extended operations where the supraclavicular and internal mammary areas are attacked are thoughtfully considered and the pros and cons weighed.

The illustrations are generous in number and excellent in quality. The type is very readable but a little too small and closely spaced. There are numerous tables of a statistical nature which are properly included in a comprehensive text.

The medical student, the general practitioner, and the surgeon will all find here material for their particular needs.

—MAX L. SMITH Lt Col MC USA

February 1957

REVIEWS OF RECENT BOOKS

**DISEASES OF THE HEART** by Charles F. Brinkley M.D. 4th edition 1956  
Pages illustrated W. B. Saunders Co., Philadelphia Pa. 1956. Price \$18

The second edition of this well known text contains a new section on the graphic methods of cardiac examination consisting of discussions of roentgen examination, electrocardiography and vector cardiography and ballistocardiography, phonocardiography and cardiac catheterization. The pages are larger and two columns per page have replaced the single column. Because of increase in size the text is about 25 per cent more material per page and there are 57 more pages than in the first edition. Larger, bold face type has been used for headings and subheadings.

By necessity the section on electrocardiography and vector cardiography is abbreviated but it serves the useful purpose of presenting the reader to the author's opinions so that interpretation of the electrocardiogram is facilitated.

Classical references have been retained but bibliographies have been greatly expanded by the inclusion of many new references including the 1956 literature, making this a truly up-to-date text. New illustrations have been added and appropriate ones from the first edition have been retained.

The section on congenital heart disease has been extensively rewritten. For example the section on aortic septal defect with mitral stenosis (Lutenbacher's Syndrome) which formerly occupied about two pages has been replaced by two sentences indicating the nature of this condition. The need for accuracy in diagnosis is stressed because of the availability of corrective surgery by new techniques.

In the treatment of myocardial infarction the author still recommends the time honored method of bed rest. The "arm-chair" treatment and the misinterpretation of this method by some physicians to permit early ambulation is discussed. The author prefers the use of an anticoagulant in all cases where no contraindication exists.

The chapter on bacterial endocarditis is completely and superbly written, as one would expect in view of the great experience and extensive publications by the author on this subject.

This is an excellent student textbook and is highly recommended to all interested in heart disease.—SAMUEL H. SANDIFER Lt Col MC USA

**CLINICAL HEMATOLOGY**, by Maxwell M. Wintrobe M.D. Ph.D. 4th edition  
1184 pages 236 illustrations and 20 plates 18 in color Lea & Febiger, Philadelphia Pa. 1956 Price \$15

Dr. Wintrobe has again demonstrated his ability to present a subject of vast ramifications in such a manner that technicians, students, teachers and specialists can all reach for the same volume.

The main advances in hematology within the past few years have been clinically correlated by the revision of three chapters and the addition of two others (one on blood groups and blood transfusions and another on abnormal hemoglobin syndromes). In addition 16 illustrations 3 plates 23 tables and 1 600 references have been added. This has been accomplished with the addition of only about 30 pages and has resulted in an improvement in organization and indexing. The practical clinical aspects of radioactive materials such as iron vitamin B<sub>12</sub> and chromium have been integrated into this latest edition.

Emphasis on diagnosis and treatment correlated with the practical application of the laboratory procedures involved makes this present volume as those in the past a clinical text on hematology aimed at the practicing physician. The bibliographies for each chapter are noteworthy because of their completeness and current interest.

As with the previous editions the book should be found on every medical library shelf that is frequented by clinicians. Every physician whose duties involve hematologic aspects of disease would find it a worthy and readable reference for his personal office library.

—JULES J. MCNERNEY Lt Col MC, USA

**MEDICAL EFFECTS OF THE ATOMIC BOMB IN JAPAN** edited by Ashley W. Oughterson M D and Shelds Warren M D Foreword by Lewis L. Strauss Chairman U S Atomic Energy Commission 1st edition National Nuclear Energy Series Manhattan Project Technical Section Division VIII Volume 8 477 pages illustrated McGraw-Hill Book Co Inc New York N Y 1956 Price \$8

This book is one of approximately 60 volumes in the extensive documentation of the technical and scientific aspects of the atomic energy program during the operations of the Manhattan Project in the mid 1940's. The volumes written and still to be completed are entitled *The National Nuclear Energy Series*. This particular book is a partial summary of the very large amount of data collected by the medical members of the Joint Commission for the Investigation of the Effects of the Atomic Bomb in Japan. The data was originally reported in a six volume paper-bound series in 1951.

Although many of the individual findings have been reported separately in the Japanese and American medical literature this book summarizes pertinent findings in a well oriented readable style.

The essential findings are grouped under five chapter headings including (1) Scope of Damage (2) the Effects on Medical Care and Facilities (3) Number and Types of Casualties (4) Clinical Observations and (5) Hematology and Pathology. Representative photographs some in color have been selected to demonstrate the clinical findings. Unfortunately some of the historical aspects are lost through the omission of the original Japanese descriptions. While this book will be a valuable contribution to medical libraries for detailed studies the student is referred to the original six volume series.

From the Oath According to Hippocrates in so Far  
as a Christian May Swear It

"Blessed be God the Father of our Lord Jesus Christ who is  
blessed for ever and ever I lie not

"I will bring no stain upon the learning of the medical art  
either will I give poison to anybody though asked to do so  
nor will I suggest such a plan Similarly I will not give treatment  
to women to cause abortion treatment neither from above nor  
from below But I will teach this art to those who require to  
earn it without grudging and without an indenture I will use  
treatment to help the sick according to my ability and judgment  
And in purity and in holiness I will guard my art into whatso-  
ever houses I enter I will do so to help the sick keeping myself  
free from all wrongdoing intentional or unintentional tending to  
death or to injury and from fornication with bond or free man or  
woman Whatsoever in the course of practice I see or hear (or  
outside my practice in social intercourse) that ought not to be  
published abroad I will not divulge but consider such things to  
be holy secrets Now if I keep this oath and break it not may  
God be my helper in my life and art and may I be honoured among  
all men for all time If I keep faith well but if I forswear myself  
may the opposite befall me "

# Foreword

The United States Armed Forces Medical Journal is the medium for disseminating information of administrative and professional interest to all medical personnel of the Department of Defense. The Assistant Secretary of Defense (Health and Medical) and the Surgeon General of the several services invite all medical officers, dental officers, Medical Service Corps officers, Nurse Corps officers and officers of the Veterinary Corps of the Armed Forces and the medical consultants of the Army, Navy and Air Force to submit manuscripts for publication in this Journal.

## CONSERVATIVE MANAGEMENT OF URETERAL CALCULI

Without Use of Hazardous Instruments

EDWARD GARTMAN *Lieutenant Colonel MC USAR*

**A** REVIEW of the literature covering the treatment of ureteral calculi disclosed that an extensive collection of reports of accidents resulting from the use of mechanical extractors and dilators has accumulated.<sup>1-14</sup> The published accidents, however, must represent but a fraction of the total. I personally know of 3 ureteral ruptures, 6 ureteral perforations, and 1 loss of a Jolinson basket in the ureter, all of these injuries occurred in the past five years (1951-1956) at the hands of mature, well trained endoscopists. Moving about in the armed services one frequently meets urologists who, like myself, eschew the use of these devices, but who have signally failed to publicize the fruits of their labors. For this reason the following presentation was prepared.

### CASES STUDIED

In slightly more than five years I have treated 218 patients with 237 proven ureteral stones, in addition to some 40 other patients with colic and often with blood in the urine, in whom the presence or recent passage of a calculus could not be established. One hundred and twenty one stones were found in patients at the 141st General Hospital, Kyushu, Japan, in 35 months (35

---

Presented at the James C. Kimbrough Urologic Seminar, Walter Reed Army Medical Center, Washington, D. C., 20 September 1956.

From the 141st General Hospital, Kyushu, Japan, and U. S. Army Hospital, Fort Still, Oklahoma.

per month) and 116 at U S Army Hospital Fort Sill Okla in 27 months (4.3 per month)

The distribution of patients as to sex and type of stone—whether unilateral bilateral or recurrent—may be seen in table 1. Fourteen of the men and two of the women were Negroes the rest were white. The disparity between sexes may be accounted for by the source of the patients (military hospitals) but the relative freedom of American Negroes from the disease has previously been documented.<sup>11</sup>

TABLE 1 Distribution of 218 patients by sex and by type and number of stones removed

Sex	Number of patients	Type of stone	Number of stones
Men	200	Unilateral	219
		Bilateral	182
		Recurrent	18
Women	18	Unilateral	19
		Bilateral	18
Total	218		237

The distribution of unilateral stones between right and left sides was about equal in the men. Seventeen men gave histories of one or more previous stones while nine others were subsequently treated by me for recurrent stones. One of these nine had had 14 stones removed endoscopically or surgically or had passed them spontaneously before coming to me. I managed him through three more and found a parathyroid adenoma but some months after its removal he died of chronic renal insufficiency.

Of the 18 women 11 had stones in the right side of the urinary tract. Eight of these 11 were pregnant and two were three months postpartum. Seven women had stones on the left side among these one was pregnant and one was three months postpartum.

While it is not within the province of this article to discuss the causes of stone formation certain observations can be made on the relationship of climate and hydration to the formation of stones. The climate of northwestern Kyushu is similar to that of the southern California coast except that the former has more rain. The summers are short and mild hot weather appearing suddenly early in July after the spring monsoons and ending with equal abruptness in mid September. The summers at Fort Sill

Okla., are long, intensely hot and dry, and the temperature not uncommonly attains 90°F in early April and regularly goes over 100°F after the first of June, the heat lasting until the end of September. Temperatures over 110°F are not rare. The summer of 1954 was unusually severe with more than 40 days of maximum temperatures of 100°F or more, while the summer of 1955 was uncommonly mild and wet—there were only two days with temperatures reaching 100°F.

In the three Kyushuan summers (July, August, and September of 1951, 1952 and 1953), only 42 (34.7 per cent) of a total of 121 stones were encountered, in 1954 at Fort Sill, 42 (71.2 per cent) of a total of 59 stones were seen in June through September. The 59 stones seen at Fort Sill in 1954 amounted to almost 5 per month, while there were only 44 in 1955 (3.7 per month) and 13 in the first 4 months of 1956 (3.2 per month). Prince, Senrdino, and Wolan<sup>14</sup> presented similar evidence of the effect of a hot, dry climate. It was interesting to note that Gilbert and Gersh<sup>15</sup> saw only 3.2 stones per month at Fort Sill in a 15 month period during World War II (June 1942 to August 1943).

#### SPONTANEOUS PASSAGE

The location and fate of the 237 stones have been summarized in table 2. Almost four out of five stones passed spontaneously, the largest being 0.8 cm in its greatest diameter and originally presenting in the lower third of the right ureter. Over 90 per cent

TABLE 2 *Method of removal of 237 stones in 218 patients*

Location of stone	Number of stones	Passed spontaneously	Attempted cystoscopic removal			Open operation alone
			Succeeded		Failed (operated on)	
			On first attempt	On second or later attempt		
Impacted at meatus	28	11	15	1	0	1
Below pelvic brim	141	122	15	2	0	2
Above pelvic brim	68	53	3	2	6	4
Total	237	186	33	5	6	7

of the stones passed were less than 0.5 cm long. One stone 0.3 cm in diameter was passed within two hours of the first twinge of pain, a similar sized stone, found after hematuria was observed microscopically in a routine physical examination, was passed painlessly 105 days later, the patient experiencing

widely separated episodes of colic during this time. The majority however passed in from two to nine days, the mean was almost five days. No complications or accidents accompanied the spontaneous passage of stones.

### CYSTOSCOPIC REMOVAL

The following criteria listed in the order of weight attached to them were used as indications for intervention (1) the degree of obstruction it was believed that incomplete obstructions producing dilatations above were more urgent than completely obstructing stones suppressing function (2) the size of the stone (3) its location and (4) the frequency and severity of pain. Great reliance was placed upon intravenous urography which was regularly employed before attempting instrumentation or operation.

In handling stones endoscopically the following maneuvers alone were used. Stones projecting out of or impacted in the ureteral meatus were extracted with a cystoscopic foreign body forceps, or else meatotomy with a cystoscopic scissors and extractions were performed. No rigid or metallic instruments were used beyond visual range. For stones above the meatus a single catheter was inserted by the stone and left indwelling for from 24 to 48 hours. The stone was then fragmented by gentle manipulation with various sized catheters in sequence. Radiologically "soft" stones were snared with a lasso catheter. Small stones were rolled out in the eye of a catheter.

These manipulations were successful the first time in 75 per cent of the cases. This compared favorably with the best endoscopic results. The largest stone removed transurethrally measured 0.7 cm in its greatest diameter the smallest was a minute granule less than 0.1 cm in diameter. Only nine were greater than 0.5 cm in length. There were no complications or accidents. Five other stones ranging from 0.4 to 0.9 cm in greatest diameter were removed after two or more efforts. Two of the patients suffered attacks of pyelonephritis after unsuccessful tries but again there were no accidents. Cystoscopic attempts (six per stone) to remove six stones ranging from 0.6 to 1.3 cm in diameter from the upper ureter resulted in failure and all were removed by ureterolithotomy. These represented a rather high failure rate of 13.6 per cent. Some other cystoscopic failure rates are: Dourmashkin 5.3 per cent, Wishard 8.9 per cent, Middleton and Grua 3 per cent, Prentiss, Mullenix and Whisen and 20 per cent.

The cystoscopic failures were all accompanied by one or more attacks of pyelonephritis (15 for the group). These patients suffered considerably bad prolonged hospitalizations and in one

instance, a ureteral perforation almost occurred. The largest stone in the group, 1.3 cm long, was pulled down to the middle of the pelvic ureter with a lasso. At this point one of its prongs became impaled in the ureteral wall, but the No. 00 silk thread tore before further damage could be done. The lasso tore frequently, invariably under tensions too low to injure the ureter—its major advantage. These six stones were handled at the 141st General Hospital. As a result of our experience with them, all stones seen since then in the upper ureter with diameters greater than 0.5 cm have been removed by open operation without further delay. Despite this change in attitude, I have done only four ureterolithotomies at Fort Sill.

### SURGICAL REMOVAL

There were 13 ureterolithotomies, or 5.5 per cent of the total series. At the time of operation, the stones were located as follows: ureteral meatus (large ureteroceles), 1; pelvic ureter, 3 (figs 1 and 2); upper ureter, 9. There was only one complication. Fol-

*Figure 1 Intravenous urogram showing large stone in left ureteral diverticulum in a 24 year old white woman. Stone vaginally was removed transvesically.*

Following removal of a stone in the upper ureter on 7 January 1956 a persistent fistula developed. On 20 January the patient was cystoscoped and a millet sized spicule not counted as one of the 237 stones was found in the ureteral orifice. This was removed and a No. 6 French ureteral catheter was left indwelling for 48 hours. The fistula closed promptly and the patient returned to duty on 23 January to be readmitted the following evening with an abscess in the fistulous tract. The abscess was evacuated and the patient discharged on 27 January. He has been well since. The origin of the spicule could not be determined, because a No. 6 French catheter had been passed up into the pelvis and down into the bladder at operation.

Figure 2 Plain plate showing large dendritic calculus in pelvic ureter of a 19 year old postpartum white woman. Extraperitoneal ureterolithotomy resulted in uneventful convalescence.

## DISCUSSION

The incidence of the spontaneous passage of ureteral stones in previously published series ranged from 6.2 per cent (Dourmashkin) to 53.7 per cent (Prentiss, Mulloix, and Whisenand), while intervention by open operation ranged from 7 per cent (Wishard) to 54.3 per cent (Kittredge and James<sup>10</sup>). Of the stones in my series, 78.5 per cent came out unaided, and a mere 5.5 per cent required open operation. This probably can be attributed to the fact that in the military all patients with ureteral calculi are turned over to the urologist immediately, whereas in civilian practice only the more difficult and stubborn cases are seen by the urologist. Accordingly, the present series probably represents a truer picture of the disposition of ureteral calculi than those hitherto published.

## SUMMARY AND CONCLUSIONS

In a series of 237 ureteral calculi in 218 patients, 186 stones passed spontaneously without accidents or complications, 38 were removed cystoscopically (33 on the first attempt, 5 on a second or later attempt), and 13 were removed by ureterolithotomy (6 after cystoscopic failure and 7 by operation alone). Two of the patients whose stones required more than one cystoscopic attempt had attacks of pyelonephritis following unsuccessful tries, but there were no accidents. Those patients in whom cystoscopic removal failed suffered 15 attacks of pyelonephritis, and there was one near perforation of the ureter. One patient, a chronic stone former, died of renal insufficiency some months after the removal of a parathyroid adenoma. There were no other deaths.

This series demonstrates that ureteral stones can be adequately and safely handled without the use of hazardous instruments.

### ARE SAINTS WELL ADJUSTED PEOPLE?

"The easy way to relieve stress is to yoke mental science and modern techniques of persuasion to the task of making everyone well-adjusted to everyone else. This is not only emptying it is in a measure useful and indeed necessary for our growing organisation demands ever more conformity ever more mutually adjusted specialism ever more acceptance to make it work at all. There seems ever less time for doubt and for dissent. Yet both Christian and scientific insights warn us that along that road lies mortal danger not only for the individual but for society also.

"For saints artists creative thinkers and above all martyrs are seldom well adjusted people and no civilisation can do without them. Least of all ours which changes faster than any has before. These are they who incubate tomorrow's orthodoxies through their heretic phase—for all orthodoxies were heresies when they were born. These are the deviants from among whom spiritual evolution will find the material for her next big adaptation. In every age so far enough have escaped martyrdom to fertilise the next. It would be ironic if we alone were efficient enough to make ourselves spiritually barren."

—SIR GEOFFREY VICKERS V C M A

# SERUM GAMMA GLOBULIN IN THE BURNED PATIENT

With Special Reference to Septicemia

BERNARD BALIKOV *Captain MSC USA*

CURTIS P. ARTZ *Lieutenant Colonel MC USA*

DONALD F. SOLOMOTO *Specialist Third Class USA*

THE PRESSING problem of septicemia in the burned patient has been re-emphasized in a recent report by Liedberg and associates.<sup>1</sup> Because many antibodies are concentrated in the serum gamma globulin (GG),<sup>2,3</sup> it was believed that a study of changes in this protein fraction might aid in understanding some of the biochemical responses of a burned patient to septicemia. As a burn study center, this unit had material readily available. The following is a report on 19 patients who had burns ranging from minimal to lethal. Of these, 7 had septicemia, 11 did not, and in 1 septicemia was doubtful.

## MATERIALS AND METHODS

It was possible for many of the patients studied to be admitted to this unit within 24 hours after their injury because of an efficient air evacuation procedure set up by this organization. Only four patients were admitted 10 or more days postburn. All data were collected within a period of four months. The importance of these factors is that they allowed for essentially similar therapy for all patients studied. Since administration of fluids to the burned patient is intensive for at least several days following the trauma, differences in therapy could conceivably vary the results of a study, particularly on blood constituents. The therapeutic regimen followed on these patients was essentially that given by Reiss and associates.<sup>4</sup>

GG was assayed by a recently described method<sup>5</sup> which consists essentially of salt fractionation by the method of Volfson and associates<sup>6</sup> followed by a modification of the tyrosine color

---

From Surgical Research Unit, Brooke Army Medical Center, Fort Sam Houston, Tex. Capt. Balikov is now assigned to Walter Reed Army Institute of Research, Washington, D. C.

reaction of Greenberg<sup>7</sup> applied to the isolated protein Recoveres of GG added to serum or from artificial mixtures of albumin and globulin averaged about 85 per cent.<sup>8</sup> The precision of this method (twice the standard deviation) is  $\pm 0.14$  g per 100 ml of serum.<sup>9</sup>

Total protein (TP) was estimated by a procedure which was also based on the tyrosine color reaction of Greenberg. This method has been modified for adaptation to the Coleman Jr spectrophotometer by adjusting volumes of sample and reagents such that most readings fall in the center of the spectrophotometer scale when read at a wave length setting of 670 millimicrons. Thus 0.5 ml of serum is made up to 20 ml with isotonic saline. One ml of this solution is used for color development by addition of 22 ml of water exactly 1 ml of 5 normal sodium hydroxide and 1 ml of phenol reagent. One milliliter of a standard containing 0.1 mg of tyrosine in 0.1 normal hydrochloric acid is treated precisely as is the saline serum solution. The blank which is treated in the same fashion consists of 1 ml of isotonic saline.

All GG and TP analyses were done on serum from blood samples drawn after an overnight fast.

## RESULTS

Table 1 summarizes our results. The burn equivalence used is adapted from Bull and Squire,<sup>10</sup> who weight second degree involvement as equivalent to one fourth the severity of third degree involvement. This serves to define the over all seriousness of an injury in which there is both second and third degree burns.

The GG values in table 1 are presented as a scattergraph in figure 1 to demonstrate the initial drop to subnormal levels which is characteristically followed by a rise with increasing time postburn. Although the serum GG may be normal on day 0 (0.7 to 1.7 g per 100 ml of serum), sometime between day 0 and day 10 the level will tend to drop below normal at least for burns of a burn equivalence greater than 5. This level is taken as the cutoff point since a patient with a burn equivalence of 4 did not show this phenomenon although one with a burn equivalence of 6 did.

The one low GG value in the lower right hand corner of figure 1 was obtained on the 32d postburn day for that patient. The reason for such a low level at that late date is not apparent. This patient did not have septicemia and was doing well at the time the blood was drawn. Seven days prior to this sampling a GG level of 1.4 g per 100 ml of serum was found, and some 30 days later a value of 1.4 was again observed. Unfortunately no

\*Italicized results were obtained on samples drawn while a patient had septicemia

Dash lines are under results obtained on samples drawn from a patient with questionable septicemia

assays were taken shortly after obtaining the remarkably low value, and it remains an enigma

The ratio GG/TP (fig. 2) shows precisely the same relationship with days postburn as does GG alone (fig. 1)

On glancing at the GG values in table 1 for the period 0 to 7 days postburn, it appeared that levels were particularly low on patients with septicemia. However, since all values tend to be

Figure 1 The change of serum gamma globulin levels with days postburn.

low during this period a statistical analysis was employed to determine the confidence one could place in this observation. Values obtained during the first 10 postburn days were analyzed according to the method described by Mainland<sup>1</sup> and the results are shown in table 2. The P value indicates a significant difference between the two groups at the 5 per cent level and leads to the conclusion that during the first 10 postburn days although low serum GG levels are to be expected these values will be still further depressed if septicemia is present.

Figure 2 The change of the ratio (gamma globulin/total protein) with days postburn

An analysis of the GG/TP ratios identical to the above analysis of GG levels reveals the following

$$t=1.54$$

$$P\text{-between } 0.1 \text{ and } 0.2$$

This P value does not indicate a statistically significant difference between the two groups. It does, however, point to a likely tendency for ratios which, although low during the first 10 postburn days, may be still lower in the presence of septicemia.

Figure 1 The change of serum gamma globulin levels with days postburn.

low during this period a statistical analysis was employed to determine the confidence one could place in this observation. Values obtained during the first 10 postburn days were analyzed according to the method described by Mainland<sup>1</sup> and the results are shown in table 2. The P value indicates a significant difference between the two groups at the 5 per cent level and leads to the conclusion that during the first 10 postburn days although low serum GG levels are to be expected these values will be still further depressed if septicemia is present.

The GG/TP ratios show no trends whatever when correlated with the seriousness of the burn, during any postburn period (table 3)

### DISCUSSION

The reason for the fall in serum GG levels during the first several days postburn is not known. Dilution subsequent to fluid therapy probably plays a role, but this would not explain the drop in the GG/TP ratio. Gjessing and Chnautin<sup>11</sup> noted a similar drop in the GG levels of burned rats and stated that this is also true in the dog. Prendergast, Feinichel, and Daly, although principally interested in GG levels some 15 to 20 days postburn, have recorded values earlier as well (using an electrophoretic procedure). A study of either their table or their graphs indicates precisely the trend noted above, namely, a drop in the serum GG sometime between day 0 and about day 10, followed by a rise to normal or above.

It is of interest that the GG/TP ratio also falls during this early postburn period. Since it is well known that the plasma TP concentration is depressed at this time, it must mean either that loss of the other protein fractions are lost or that some of these other protein fractions are more efficiently replaced than GG. If the answer is that less "other protein" is lost, it is not likely to be a leakage phenomenon since the GG molecule is among the largest of the protein fractions and so would be less rather than more likely to leak out of the vascular system. This differential loss, therefore, would be more readily explained on the basis of a more rapid metabolism of GG.

However, it is quite possible that the mechanism does not involve loss as much as it does replacement. Replacement can be accomplished either by infusion of protein solutions or by some in vivo metabolic process. Gjessing and Chnautin, in their work with burned rats, found a percentage fall in the plasma albumin and GG and a percentage rise in the alpha and beta globulin fractions (with reference to TP). These rats received no transfusions. This would increase the likelihood of a replacement phenomenon of the relatively more concentrated fractions being the result of some in vivo metabolic process rather than the result of therapeutic infusions. As an in vivo phenomenon, the cause can be either inadequate formation or inadequate distribution. The latter possibility is based on a preliminary report by Francis, Hawkins, and Wermall,<sup>12</sup> who present evidence for the presence of an extravascular antibody in the rabbit. Also, Miller and associates<sup>13,14</sup> report that in rats GG is formed almost exclusively in extrahepatic tissue. It is thus possible that, even though GG is formed, it does not find its way into the blood.

The work of Prendergast, Fenichel, and Daly<sup>12</sup> led us to seek a relationship between the burn equivalence as a measure of the seriousness of a burn and the serum GG level. The days post burn were divided into 7 day periods (table 1) and the mean GG for an equivalence of 20 and below was compared with the mean for equivalences of over 20, again by use of the *t* test. Contrary to the conclusions drawn by Prendergast, Fenichel, and Daly, it can be seen (table 3) that for every period except the one from 29 to 35 days the mean GG level for the low equivalence burns is actually greater than for the high equivalence burns.

TABLE 3 *Correlation of serum gamma globulin and gamma globulin to total protein ratios with extent of burn*

t		0		1.35		0.82		0.41		1.25
P				0.2-0.3		0.4-0.5		0.6-0.7		0.2-0.3

there is a relationship between the increase in GG level and the severity of the burn. Contrariwise, we find a tendency for lower GG levels with increasing severity of burn (table 3). It is possible that this discrepancy is the result of differences in analytical methods. Prendergast, Fenichel, and Daly used an electrophoretic method, whereas we used a salt fractionation method. The principal difference in these methods is that we may be measuring approximately 15 per cent non GG protein as compared with electrophoretic separations. However, this "contaminant" is not dependent upon albumin concentration and so is presumably dependent only upon globulin changes.<sup>4</sup> Since Prendergast, Fenichel, and Daly found that other globulin fractions also increase with the GG (though not as markedly), it is believed that methodologic differences are not likely to contribute greatly to differences in findings. Nonetheless, one should not dismiss this possibility since, in the special case of a burned individual, these methodologic differences may be exaggerated.

It is also possible that the discrepancy in our findings is due, not to methodologic differences, but to differences in therapy. These workers<sup>4</sup> stress the use of repeated whole blood transfusions, whereas our regimen stresses administration of plasma expanders and large quantities of electrolyte solutions in addition to blood.<sup>4</sup> This difference is difficult to evaluate because of the large role usually played by clinical judgment in deciding on therapy for any particular patient. In general, the total proteins reported by Prendergast, Fenichel, and Daly for their serious burns are considerably higher than ours, so there is a good possibility that their therapeutic regimen does favor protein replacement more than does ours, and that this in turn contributes to the lack of agreement on relating GG levels to the severity of the burn.

Another variable is the classification of a burn with regard to seriousness of injury. The burn equivalence previously mentioned is an attempt to make this observation more objective. However, this system was used only by our group so that we cannot be sure that a burn called very serious by one group would be similarly listed by another. It was found that differences in handling data did not contribute to differences in findings. They analyzed their data by observation. We grouped their patients as four with "severe" and four with "less severe" burns (according to their own descriptive classification) and divided the GG data accordingly. The levels in each group were averaged and subjected to the *t* test. Differences between the groups were statistically significant (*P* value of between 0.02 and 0.05). To summarize, it would appear that differences between our results and the observations of Prendergast, Fenichel, and Daly are

stream To summarize the differential depression of the serum GG in the early postburn period is most likely due to one or more of three factors (1) a high rate of removal by some metabolic process (2) a low rate of formation or (3) inadequate movement of GG from extravascular to intravascular spaces

The additional drop in GG levels seen in the presence of septicemia occurring during the first 10 days postburn is surprising because normally one expects to find an increase in the presence of an infectious disease Since sodium is retained in such cases and since it is common practice to intensify administration of fluids to burned patients with septicemia dilution may again be a significant factor However simple dilution does not explain the tendency for the GG/TP ratio to fall It is possible that the initial low GG levels seen on all burned patients are related (in addition to a dilution phenomenon) to a stimulation for production of plasma GG to which the organism is already unable to respond Thus the additional stimulus of an infectious condition may be incapable of evoking an increased response In the usual situation even though the complex formed of an antigen antibody reaction *in vivo* may remove some circulating GG apparently the organism is stimulated to a further production of antibody resulting in a net increase of plasma GG Since the organism is incapable of such an increased production in the early stages of a burn the net effect of removing antibody GG by formation of an antigen antibody complex is to lower the GG level

From figure 1 it can be seen that the rise in GG with time postburn is characteristic not only of patients who recuperate but also of those whose condition deteriorates and who eventually die In this latter group are three patients who lived longer than 10 days (burn equivalences of 19, 27, and 33 of table 1) Although patient 13 did not have a GG assay until his 19th postburn day there seems no reason to believe his earlier GG levels would not have fallen into the usual low range With only three patients in this category one cannot draw conclusions with a great deal of assurance However it would appear that whatever the nature of the antagonism to the production of plasma GG in the immediate postburn period it is the result of the burn insult per se Thus despite other complications as the organism recovers from this shock it again becomes capable of responding to the demand for plasma GG

The above considerations may make it worthwhile for clinicians to consider the use of GG preparations as part of their therapeutic program during the immediate postburn period

As pointed out under "Results" we have been unable to confirm the observation by Prendergast, Fenichel, and Daly that

probably due to differences in therapy with contributions to this discrepancy from differences in method and from lack of standardization in classifying the severity of the injury

It has been pointed out that there is a statistical difference between the GG levels of patients with and those without septicemia during the first 10 postburn days. One may ask if this drop in GG level is a sensitive index of septicemia. The mean for the nonsepticemic group is 0.9 g per 100 ml of serum with a range (twice the standard deviation) of from 0.1 to 1.7. Thus a value must be 0.1 or less to be a statistically significant indication of septicemia. However the mean for the septicemic group is 0.5 with a range of from 0 to 1.2 so that there is a considerable overlap of values. Therefore during the first 10 postburn days a GG level of 0.1 or less is most likely related to septicemia but levels between 0.1 and 0.5 must be considered doubtful. Since very few values on patients with septicemia are 0.1 or less (table 1) this test cannot be considered a sensitive index of septicemia.

#### SUMMARY

During the first 10 postburn days, there is a tendency for serum GG levels to drop below normal in burns classified as having a burn equivalence greater than 5.

If septicemia is present during the first 10 postburn days the serum GG level will tend to be exceptionally low. Values as low as 0.1 g per 100 ml of serum or less are usually associated with septicemia. However a low GG concentration is not a sensitive index of septicemia.

There is a tendency for the ratio GG/TP to be low during the first 10 postburn days particularly in the presence of septicemia. The significance of this observation is discussed.

After the first 10 postburn days the serum GG concentration will increase regardless of whether the condition of the patient improves or deteriorates.

No relation can be found between the seriousness of a burn as determined by the burn equivalence and either GG values or GG/TP ratios at any stage of a burned patient's recovery. The reasons for the disagreement between this finding and the reports of other workers are discussed.

## PART A: B PERFORMANCE

977

2 *Double names* Four double names were given, and then only the surnames were repeated in a different order, while the subject had to write down the first names (fig. 1f)

3 *Object number* An object was given with a number, and then the object only was repeated in a different order, while the subject had to write down the corresponding number (fig. 1g)

### Time Perception Tests

In a third group of experiments time perception was tested

1 *Free estimate* The subject had to estimate an interval of one minute, and the actual time was recorded

2 *Tapping* The subject had to tap out 60 seconds on a counter, and the actual time was again recorded "

### Muscular Co-ordination Tests

The fourth group of tests involving muscular co-ordination was as follows

1 *Passing ball* A small rubber ball was passed through a 1 foot long tube, which had a slight elastic contraction at the end, so that the ball was stopped but could be pressed out easily. The number of passes per 30 seconds was determined

2 *Punchboard* A plastic board had three holes arranged as a unilateral triangle with a side length of 4 inches. A metal stylus fitted the holes and a shoulder stopped the punch at a depth of 3/16 inch. The number of punches per 30 seconds was counted

3 *Rotary pursuit device* The subject had to follow with a stylus an irregular line on a rotating kymograph. The mistakes were automatically recorded on an Esterline Angus armeter

### Reaction Time Tests

Reaction time was tested two ways

1 *Simple reaction time* A 360 millisecond time clock was arranged with two interruption switches. The operator started the clock. The subject, when seeing the hand of the clock moving, stopped it by pressing his switch

2 *Choice reaction time* The same arrangement as in simple reaction time was used. However, this time the subject was told to respond only to one of two sounds of slightly different frequencies. The reaction time and the number of false reactions were recorded

### Reflex Activity

*Patellar reflex* was determined by having a percussion hammer mounted as a pendulum and moving through a fixed arc hit the

2 Number or letter groups In this test four groups of numbers or letters were given of which three had a common pattern. The subject had to cross out the one that did not fall in line (fig 1B)

3 Number or letter sequence In this test each group had a periodically repeated pattern and the subject had to fill in the letter or number that would follow logically if the pattern were maintained (fig 1C)

4 Code substitution Three lines were given and the fourth one had to be filled in. The first line consisted of the alphabet in order. In the second line numbers were given corresponding to each letter. The third line gave an arbitrary combination of letters and the corresponding numbers had to be filled in from the code given in the upper two lines (fig 1D)

Pain and control values refer to number of mistakes and standard error of the difference.

tendon with controlled force. The movement was registered by fixing a string to the heel which was then converted into vertical movement and registered on a kymograph.

**Skin flare.** The threshold of skin flare was determined with an electrically heated probe. The meter reading of the first skin flare reaction was recorded.

#### Work Performance, Respiratory Function and Pulse Rate

Finally, the effect of pain on rate of performance and mechanical efficiency on a stationary ergometer bicycle was determined. Respiratory measurements were made with a Hutchinson respirometer. For the oxygen analysis a Beckman model D oxygen analyzer was used. Work was determined as revolutions per 90 seconds on the ergometer bicycle (Kellso 19). Data were collected during a 90 second pre-exercise period for respiratory rate, respiratory minute volume, oxygen concentration of expired air, and pulse rate. Recordings were continued during the 90 seconds of exercise. The postexercise period started 30 seconds after the end of exercise and lasted for 90 seconds. Pulse rate was determined 30, 90 and 150 seconds after the end of exercise and all respiratory data were collected as above. Pain was produced only during the exercise period while in the control runs the physical conditions were the same but the painful stimulus was omitted.

### RESULTS

Table 2 gives the results of the first five tests on rate of mental performance. Part of the values are given as the number of problems solved in a given time period and part of them as the time needed to solve a given number of problems. In all tests there is a tendency for the rate of performance to be lower in the presence of pain, but this difference is not significant. Even if all test scores are combined there is no significant difference between the pain and no-pain conditions at the 5 per cent level of confidence.

Table 3 gives the combined results for all tests on accuracy of performance: the number of mistakes. We can divide this table into two groups of tests. In the first six tests the intensity of pain is directly related to the degree of interference, while in the last three tests even a mild pain causes a significant decrease in performance. All of the first six tests probably involve more of a mental effort than the simple crossing out of "f" of the last group. Higher and lower mental tasks are used in the same sense as intelligence tests are used to determine mental development in children. It is believed that in these higher mental tasks the subject concentrates so much on the problem that he ignores a mild pain, and interference appears only when the pain is of such

TABLE 5							
THE EFFECT OF PAIN ON MUSCULAR COORDINATION (26 subjects)							
Type of Test	Type of Pain	No tests	Pain	Control	s e d	t	p

THE EFFECT OF PAIN FROM ICE WATER ON REACTION TIME							
	No Subjects	No tests	Pain (msec.)	Control (msec.)	s e d	t	p
Simple reaction time	18	540	185.9	177.2	5.85	1.49	0.50
Choice reaction time	13	256	292.0	273.6	7.31	2.62	0.03

as the effect of pain is concerned, there is some support for Lemmon's<sup>10</sup> findings that simple reaction time parallels memory and choice reaction time parallels reasoning. The tests on the patellar reflex did not produce any significant results (table 8).

TABLE 8							
THE EFFECT OF PAIN FROM A PRESSURE CUFF ON REFLEX ACTIVITY							
	No Subjects	No tests	Pain	Control	s e d	t	p
Patellar reflex	11	165	8.5	10.4	1.35	1.65	0.10
Skin flare	12	24	51.8	49.0	0.87	3.22	0.01

cm meter reading

The skin flare threshold was significantly increased in the presence of pain (table 8). This might be an indication of a peripheral

intensity that it cannot be ignored. However if not much mental effort is required, then even a mild pain causes sufficient distraction to affect performance.

Table 4 gives the effect of pain on memory tests. No significant effect of pain was observed. In these tests pain was applied during the period of retention and during the recall period. Therefore the data indicate that neither of these two components of memory are affected by pain.

$d = \frac{\text{Pain} - \text{Control}}{\text{S.D.}}$   
Standard error of the difference

When time was determined by tapping out 60 seconds, no difference between pain and control was found. When the subject was asked to estimate one minute, there was a significant increase with pain due to cold. This is considered an indication of over compensation for the apparently slow passage of time in the presence of pain (table 5).

TABLE 5 THE EFFECT OF PAIN FROM ICE WATER ON TIME ESTIMATION						
(1 min)						
Typ of Test	Sbjcts	Trials	P (sec)	C (sec)	S.D.	d
Tapping	16	16	64.3	69.5	5.23	0.99
Free Estimate	16	16	73.9	65.6	8.88	2.14

In the tests on muscular coordination (table 6) it was found that the degree of interference in the presence of pain varied with the type of test. Passing the ball is a very easy test, and here no significant effect was observed even during a 4 dol pain. The punchboard test requires more precision and here the effect of pain is barely significant. The rotary pursuit device, which is still more refined as far as coordination precision steadiness and attention are concerned, showed a highly significant degree of interference. This differentiation as to the degree of refinement of these tests is used in the same way as tests of muscular coordination are used to determine the performance level of children. Considering the three different pain intensities used in these tests, it becomes clear also that the degree of interference depends on the pain intensity being used.

inhibitory effect of pain as indicated by the recent findings of Galambos Sheatz and Vernier.<sup>1</sup> However, at present we cannot be sure whether this is not purely a vasoconstrictor effect due to epinephrine released under stress.

Table 9 shows that pain does not affect work performance as measured with an ergometer bicycle under these experimental conditions. Table 10 shows that the respiratory rate was increased in pain during but not after exercise while the tidal volume (table 11) shows no significant change the respiratory

minute volume (table 12) is markedly increased during as well as after exercise. Oxygen concentration is changed only in the pain produced by the pressure cuff during exercise (table 13). Oxygen consumption during exercise is the same with or without pain but when pain is present during exercise the oxygen consumption is markedly increased during the postexercise period (table 14). Also under those conditions postexercise pulse rate is significantly increased (table 15). None of the above changes can be seen in the experiments with mild pain induced by the headgear. The findings are considered an indication that for

This does not mean that the process underlying the individual performance tests is necessarily different, and the point of interference in the presence of pain might well be common to all of them. However, it is believed that with our present state of knowledge no conclusion regarding any specific type of performance can be drawn without testing this particular performance directly. The results show also a different type of response to pain for these two groups of tests.

In addition to these limitations, there are some specific restrictions due to the particular methods used in this investigation.

- 1 The subjects of these experiments were a selected group, limited in age and sex. This was done intentionally to get sufficient uniformity so that the data could be analyzed statistically.

- 2 The subjects for these experiments were volunteers. Probably in a volunteer group the fear of pain is not as pronounced as in the general population. Closely associated with the fear of pain are the emotional component of pain and the reaction to pain which, then, in our selected group are probably less pronounced than in the rest of the population.

- 3 In these tests we used only experimentally induced pain in which the subject is fully familiar with the cause of the pain. He knows how long the pain will be present, and that no danger is connected with it. Therefore, the threat content of this is not as marked as that of pain from disease or trauma of identical intensity.

All of these factors tend to decrease possible effects of pain on performance as measured in this study. Therefore, what is not significant in our results may become significant under less restricted conditions. However, it is unlikely that any significant changes found here might not hold up in a less selected group.

Another difficulty in the interpretation of our results is the problem of pain intensity. We used in these tests three different types of pain, which clearly represent three different pain intensities. However, they differed in other respects as well as in pain intensity. Therefore, any interpretation of the effect of pain intensity must be made with this limitation in mind.

#### SUMMARY

Using various types of pain stimuli and taking each subject as his own control, the following observations regarding the effect of pain on performance were made:

- 1 Tests involving primarily memory and the speed of performing various mental tasks are not affected by simultaneous pain.

- 2 In tests involving simple mental tasks, the number of mistakes is increased in the presence of pain, and this increase

short periods of exercise pain does not affect the amount of work performed. However the effects on the respiratory and cardiovascular system show that the efficiency of performance is decreased.

## DISCUSSION

In this study certain changes of performance in the presence of pain were demonstrated. However this is no indication that the subject's capability to perform such a task is impaired. The results might be explained equally well by lack of concentration. This study deals with pain and the resulting changes of performance without any attempt to determine any of the intermediate steps or mechanisms.

A variety of tests was used in this investigation, some of a more physical character and others of a more mental character.

### PROGRESS IN PREVENTIVE MEDICINE

"The progress of medicine is strikingly revealed when the present is compared with the past. The life expectancy of an infant at birth in the early days of the United States was actually less than the age at which the medical student of today completes his formal education. He can afford to prolong his schooling far beyond what would once have been considered reasonable because the duration of his expected productive period has been so greatly prolonged.

The importance of preventive medicine is appreciated only if one recalls the pestilences and similar calamities of the past. Further reduction of the mortality and morbidity from accidents is obviously possible. The prevention of such conditions as arteriosclerosis and hypertension will be more difficult."

—JAMES WATT M D

in *Journal of the American Medical Association* p 1351 Aug 4 1956

appears to be independent of the pain intensity (up to 4 or 5 dols)

3 In tests involving higher mental tasks, the number of mis takes is increased and this increase corresponds roughly to the pain intensity

4 Time estimation is increased which is considered an over compensation for the apparently slow passage of time in pain

5 Pain impairs the performance in tests of muscular co-ordination. The degree of interference apparently increases with the pain intensity and also with the degree of refinement of the task to be performed

6 Simple reaction time is not affected by simultaneous pain while choice reaction time is prolonged

7 The mean amplitude of the patellar reflex is not significantly affected by pain while the threshold of the skin flare reaction is significantly raised

8 In short tests of work performance the total work is not significantly altered by simultaneous pain. However the efficiency of performing the work as indicated by changes of the cardiovascular and respiratory system, is markedly decreased by simultaneous pain

establish conclusively a cause and effect relationship between the examination data and the predictions because unrecorded perceptions and impressions may have played a major role in the final judgment of at least some of the psychiatrists. However, if it can be demonstrated that certain elements of the family history, preservice adjustment, or clinical impression regularly influenced the psychiatrists to make erroneous deductions of future duty performance, this knowledge could be used to improve psychiatric screening techniques.

### METHOD

Items of the psychiatric examination, psychiatric predictions, and performance ratings were coded and punched on standard electric accounting machine cards and correlations made. Differences in predictions among the six psychiatrists who participated in the study were explored. For simplicity, the only prediction used was prediction for service in a noncombat area, however, relatively little variation was noted between predictions for combat duty and those for noncombat assignment.

### RESULTS

An obvious over all result should be noted before any details are given. The psychiatrists predicted satisfactory performance for only 76 per cent of the sample, whereas 89 per cent rendered adequate service. This underestimation of satisfactory performance indicates that the psychiatrists tended to overemphasize unfavorable aspects of histories, interview impressions, or other examination findings.

**Family History** In estimating potential adaptability, it is common for psychiatrists to be negatively influenced by a history of unfavorable or traumatic circumstances in the early formative years. Table 20 illustrates the relationship of adverse childhood situations to psychiatric predictions of future effectiveness and to ratings of actual performance. The results indicate that the psychiatrists participating in this study were only mildly influenced by the past environment. When the individual categories are compared with the over all group it will be noted that there were six categories which had a P value indicating a significant difference (using .05 level of confidence) from the entire group in the percentage *predicted* to give satisfactory duty. Only two of these categories had a P value indicating a significant difference from the total group in the percentage who *performed* satisfactory duty. One may conclude from these findings that major sources of error in psychiatric prediction cannot be charged to an overemphasis on unfavorable childhood events as deleterious to successful military duty, although admittedly there was some overweighting of the importance of religion and the mother-child relationship.

# PSYCHIATRIC PREDICTION AND MILITARY EFFECTIVENESS

## Part III \* Factors Influencing Psychiatrists

ALBERT J GLASS Colonel MC USA  
FRANCIS J RYAN Captain, NSC USA

ARDIE LUBIN Ph D  
C V RAMANA

ANTHONY C TUCKER Colonel NSC, USA

A STUDY reporting the ability of psychiatrists to forecast the future military usefulness of recent inductees was initiated in 1951<sup>1,2</sup>. In that study 500 randomly selected basic trainees were evaluated by military psychiatrists at six Army training centers. Findings of the psychiatric examinations were recorded on standardized forms to facilitate a uniform collection of data which in addition to a narrative summary in each case included (1) background information and preservice adjustment (2) the early formative environment and preservice adjustment (2) clinical impressions of the psychiatrist as to the degree of psychopathology if any and the intelligence level and (3) the psychiatrist's estimation of the subject's future military effectiveness when assigned to a combat zone or to a noncombat area.

After the subjects had completed two years of Army service their performance of duty was rated from personnel and medical records and compared with the psychiatrists' predictions that were made early in basic training. Results clearly indicated that experienced military psychiatrists were unable to efficiently identify the potentially unsatisfactory soldier.

This report represents an effort to explore some of the causes for error in psychiatric prediction by determining which items of recorded information that were available to the psychiatrists had the largest apparent influence upon their estimation of the subjects' later military usefulness. Such an investigation could not

Part I and II were published in the October and November 1956 issues of this Journal.  
From Walter Reed Army Institute of Research, Washington, D. C.

Table 21 demonstrates the relationship of faulty preservice adjustment to psychiatric prediction and performance. A rating of questionable or impaired preservice adjustment was scored on the basis of the following criteria:

TABLE 21 *Relationship of preservice adjustment to prediction and performance*

Category	Totals	Satisfactory duty			
		Predicted		Performed	
		Per cent	P value	Per cent	P value
Entire group	305	76		89	
Questionable or impaired adjustment to					
Community	36	28	.001	67	.001
Work	71	32	.001	77	.001
Social and recreational activities	79	46	.001	80	.01
School	152	49	.001	80	.001
Parental family	86	56	.001	80	.01
Sex	124	69	.05	89	ns

P values indicate the statistical significance of the differences between the per centages of individual items of prediction and performance and the percentages of their respective total groups.

*Community* Delinquency, overt crimes, or troublemaking short of criminal behavior (alcoholism, public brawling, et cetera)

*Work* Inability to maintain steady employment (floating from job to job), inadequacy, or continued difficulties with employers or employees

*Social and recreational activities* Seclusive, overly aggressive or hostile behavior or absence of recreational life

*School* Consistent pattern of failure repeated truancy, or serious disciplinary difficulties

*Parental family* Repeated running away from home, incessant quarrels with parents, or excessive dependency upon family

*Sex* Repressed sexual drive (manifested by lack of sexual activity and overly moral attitudes), excessive preoccupation with sex or persistent overt homosexual drives

It is evident from table 21 that, as usual, psychiatric prediction was strongly influenced by disturbances in preservice adjustment.

P values indicate the statistical significance of the differences between the percentages of individual members of predicted and performed groups respectively for 1st group

**Preservice Adjustment** Probably the most frequently used indicator of future effectiveness is past performance. In this connection adjustment to school and work, social and recreation habits, and degree of conformity to community customs are considered to represent reliable patterns of behavior that are likely to be repeated even under quite different circumstances. This from both a common sense viewpoint and personality theory previous adaptability is used as a rational basis for acceptance or rejection by employers' admission to college promotion even financial risk.

Table 21 demonstrates the relationship of faulty preservice adjustment to psychiatric prediction and performance. A rating of questionable or impaired preservice adjustment was scored on the basis of the following criteria:

TABLE 21 Relationship of preservice adjustment to prediction and performance

Category	Totals	Satisfactory duty			
		Predicted		Performed	
		Per cent	P value	Per cent	P value

School	152	49	001	80	001
Parental family	86	56	001	80	01
Sex	124	69	05	89	ns

P values indicate the statistical significance of the differences between the percentages of individual items of prediction and performance and the percentages of their respective total groups.

*Community* Delinquency, overt crimes, or troublemaking, short of criminal behavior (alcoholism, public brawling, et cetera)

*Work* Inability to maintain steady employment (floating from job to job), inadequacy, or continued difficulties with employers or employees

*Social and recreational activities* Seclusive, overly aggressive, or hostile behavior or absence of recreational life

*School* Consistent pattern of failure, repeated truancy, or serious disciplinary difficulties

*Parental family* Repeated running away from home, incessant quarrels with parents, or excessive dependency upon family

*Sex* Repressed sexual drive (manifested by lack of sexual activity and overly moral attitudes), excessive preoccupation with sex, or persistent overt homosexual drives

It is evident from table 21 that, as usual, psychiatric prediction was strongly influenced by disturbances in pre

All unfavorable criteria were significantly related to rather sharp decreases in predictions of satisfactory service. Except in the sphere of sexual adjustment this judgment was confirmed at least statistically by performance rating. Here the obvious error in psychiatric prediction was not one of direction or quality but rather of degree or quantity. For example only 28 per cent of subjects with a history of questionable or impaired community adjustment were estimated to give satisfactory duty. However 67 per cent rendered adequate service. Also only 32 per cent of subjects with poor work records were considered to be potentially effective soldiers yet 77 per cent functioned satisfactorily. Similarly other categories of questionable and impaired adjustment were strongly related to unfavorable predictions but only mildly influenced performance.

This error of the psychiatrists does not disprove common sense reasoning or personality theory. Rather it highlights the unique difficulties inherent in any effort to predict the later behavior of youthful subjects. The individuals in this study whose ages ranged from 19 to 21 years had not as yet established firm patterns of adjustment but were in a formative and malleable stage and subject to change by external events and internal pressure. This transitional state was particularly evident in the sphere of sexual adjustment in which the group scored as maladjusted nevertheless rendered an average proportion of satisfactory duty. Obviously it is difficult if not impossible to estimate sexual normality in individuals in late adolescence and early adulthood.

**Psychopathology** The psychiatrists were asked to record their over all clinical impression of each subject based upon background data and interview evaluation. Table 22 illustrates the apparent effect of clinical impression upon prediction and the relationship of such diagnostic categories to performance. As expected the psychiatrists were markedly influenced by their own estimate of psychopathology to give unfavorable predictions. But performance ratings demonstrate that clinical impression was of relatively little value in identifying the unsatisfactory soldier. The results in table 22 indicate that in psychiatric prediction one should pay little attention to a clinical impression of a potential neurosis or behavior disorder represented by such diagnoses as neurotic personality, suggestive neurosis, or pathologic personality. On the other hand the presence of overt mental disease at the time of evaluation is correlated with future unsatisfactory duty particularly if the mental illness is of psychotic proportions.

**Intelligence** Intellectual ability is another commonly used index of potential capability and numerous intelligence test batteries have been devised for this purpose. The psychiatrists of

this study were also requested to record their estimation of each subject's intelligence from clinical observations made during the examination. Table 23 shows the relationship of these intelligence evaluations to the predictions that were made and to performance ratings. It should be noted that in the previously published reports of this study, the psychiatrists' clinical ratings of intelligence were highly correlated with other measures of intellectual ability such as educational attainment and the Armed Forces Qualification Test (AFQT).

Average or above	360	85	001	91	1
Below average	97	43	001	79	02
Deficient	10	0	001	70	8

P values indicate the statistical significance of the differences between the percentages of individual items of prediction and performance and the percentages of their respective total groups

The results in table 23 demonstrate a striking and significant relationship between intelligence as perceived by the psychiatrist and his prediction of later performance. Only one subject judged to be of superior intelligence was predicted to be unsatisfactory. This expectation was largely confirmed by subsequent performance. There were no predictions of satisfactory performance for the 10 subjects considered mentally deficient however 7 rendered satisfactory duty. Similarly in the below average intelligence category, only 43 per cent were considered as potentially satisfactory, yet 79 per cent functioned efficiently. This error of psychiatric prediction is again demonstrated to be due to an overemphasis on unfavorable findings as deleterious to successful military service. More specifically, the results indicate that limited intellectual ability does not necessarily imply potentially unsatisfactory duty, although average or superior intelligence is a good indication of future military effectiveness.

**Interview Behavior** Another element of the examination data which seemed to have strongly influenced the psychiatrists in assessing potential effectiveness was the interview behavior of subjects as reported in the narrative summary. Included in many of the summaries were statements by the psychiatrist relative to the impression made by the subject. Not all of the psychiatrists recorded impressions of the men they examined. Two of the psychiatrists almost never did but in 244 subjects there were sufficient data to classify interview behavior. The following assumption was tested, namely, that the psychiatrists' impressions of interview behavior during the examination strongly influenced their prediction of future military performance. Statements recorded by the psychiatrists relative to interview behavior were independently classified by two of the raters (FJR and AJG) as (1) favorable (2) mixed or (3) unfavorable. The objective validity of the rating scale seemed justified in that better than 90 per cent agreement of the ratings was found. In the few cases of disagreement a mutual decision was achieved by re-examining the record.

A typical favorable impression was as follows:  
The subject is an alert, co-operative white male who volunteered information spontaneously. He accepted the explanation for the interview situation readily and was at ease throughout the interview. He appeared of average intelligence and his veracity was high.

A mixed impression was scored in cases where the psychiatrist recorded both favorable and unfavorable qualities as follows:

The man was co-operative and alert. He volunteered little information spontaneously but answered questions readily. When talking about his parents he cried freely without any attempt at control. There was some evidence of tenseness at the beginning of the interview.

An unfavorable rating was given if the psychiatrist's impression was entirely negative, as follows:

Patient appears impulsive somewhat erratic given to fluctuating emotional attitudes. Seems to have a character and behavior disorder.

The relationship of interview behavior as rated by the above method to prediction and performance is given in table 24. The results indicate that whenever psychiatrists were favorably impressed by interview behavior to the extent of making positive statements to this effect in written summaries, successful duty performance was almost invariably predicted. A favorable interview impression apparently influenced prediction for satisfactory service more than any other component of the psychiatric examination. That such a viewpoint or orientation was valid or correct is supported by ratings of subsequent performance.

TABLE 24 *Relationship of interview behavior to prediction and performance*

Interview behavior	Number	Satisfactory duty	
		Predicted (per cent)	Performed (per cent)
Favorable	117	97	97
Mixed	80	76	91
Unfavorable	47	17	75

The potent effect of interview behavior upon prediction is further supported by the finding that when psychiatrists received an unfavorable impression of the subject, they usually predicted substandard performance (17 per cent). The negative influence of this factor on prediction was only exceeded by that of a diagnosis of overt neurosis or psychosis (14 and 0 per cent) (table 22) or of mental deficiency (0 per cent) (table 23). But unfavorable interview behavior did not correlate with subsequent performance for, as shown in table 24, 75 per cent in this category rendered satisfactory duty. As stated in previous reports of this study, satisfactory predictions based upon favorable criteria are usually valid, but unfavorable findings are not necessarily related to poor duty performance. In other words, identifying the potentially

unsatisfactory soldier is a far more difficult task than identifying the successful soldier

**Differences Among Psychiatrists** Thus far psychiatric predictions have been regarded as originating from a single source. However there were six separate sources in the form of six psychiatrists each of whom made judgments that were undoubtedly influenced by past training, previous clinical experience, and personal bias. In order to investigate the extent of error due to variability of psychiatric opinion, the proportion of success and failure that was predicted by each psychiatrist was determined (fig. 3). It is apparent that there were several quite different patterns of psychiatric prediction. For example, the psychiatrist

### PERFORMANCE PREDICTIONS BY INDIVIDUAL PSYCHIATRISTS

Figure 3. Graphs showing performance predictions by individual psychiatrists in six Army camps.

at Fort A perceived most subjects as average. Not so the psychiatrist at Fort C, who found more superior than average subjects and predicted that a large number (31 per cent) would be below average or poor soldiers. The psychiatrist at Fort D forecast almost no failures but divided his predictions almost equally among the superior, average, and below average categories.

It may be argued that the above variability in psychiatric predictions represented a different distribution of personality types in the six examined groups rather than differences derived from the psychiatrists. But figure 4 demonstrates that the performance of the various groups was relatively similar with only minor variations. Therefore, it follows that in psychiatric prediction there is included an ill defined component of personal bias.

### ACTUAL PERFORMANCE BY CAMP

Figure 4 Graphs showing actual performance in six Army camps

that varies in quantity and quality from one psychiatrist to another. This lack of uniformity in prediction among even experienced military psychiatrists is a serious and important obstacle to efficient psychiatric screening. How much more unlikely could a reasonable uniformity of judgment be attained by hundreds of psychiatrists with varying backgrounds of training and experience who would be called upon to perform a similar function at induction stations or training centers in time of full mobilization.

#### SUMMARY

Using 505 basic trainees as a sample this study has explored the relationship between certain factors (early environment, pre service adjustment, psychopathology, intelligence, and interview behavior) and the psychiatrists' prediction of military performance as compared with subsequent actual performance. Also investigated was the uniformity of psychiatric prediction as accomplished by six different psychiatrists. The objective of the study was to determine what influenced the psychiatrists in arriving at their estimations of future military usefulness in recent inductees. If it were possible to better understand the elements of the psychiatric examination that motivated the judgment of the psychiatrists, it might be feasible to demonstrate which of these influences had validity in the light of subsequent performance and which criteria should be disregarded.

It is believed that the results obtained from the study justify the following conclusions:

The examining psychiatrists in arriving at predictions of performance for inductees did not place major emphasis on unfavorable items of the family history and early environment. Although this finding was contrary to expectation, the study indicates psychiatrists were justified in their action. Background data such as emotional disturbances of family members, broken home, and a difficult relationship with the family were only mildly related to levels of performance.

Psychiatrists tended to rely more heavily on data of past performance, such as preservice adjustment to school work and the community. The psychiatrists were partially correct in that previous adjustment was more significantly related to success or failure in the Army than family background categories of information. Here the error of the psychiatrist was one of degree because a majority of subjects with a history of faulty preservice adjustment nevertheless did render satisfactory service.

Psychiatrists were strongly motivated by their own diagnoses of psychopathology or intellectual deficiency to predict unsatisfactory

factory performance. Results of this study indicate that one should pay little attention to potential neuroses or behavior disorders in psychiatric prediction. But the presence of overt neurosis or psychosis does correlate highly with future unsatisfactory duty. Similarly, limited intellectual capacity does not preclude satisfactory military service.

Psychiatrists were markedly influenced by the interview behavior and appearance of subjects. In practically all cases in which a favorable interview impression was recorded, successful performance was predicted, often in spite of unfavorable background information. This finding suggests that the psychiatrists in this study fell back on intuitive judgments and reacted more to the external appearance of subjects and behavior exhibited during the interview than to the content of the interview itself. It was found that a favorable impression was substantiated by later effective performance. However, unfavorable impressions were not equated with unsatisfactory service.

In essence, this study indicates that the psychiatrist can safely proceed upon his favorable impression of a subject but must be wary of predicting failure for a subject who exhibits unfavorable qualities. It also clearly demonstrates that there were important individual differences among psychiatrists in arriving at predictions of later performance. The six psychiatrists of this study were required to use a specifically defined examination procedure designed to produce a relatively uniform body of information from all subjects. Also, the actual performance of the rated groups was comparable. Yet, psychiatrists' predictions for those groups differed significantly, and these differences must be attributed to variations among psychiatrists in matters of personality, training, and experience.

# USE OF X RAYS AND OTHER IONIZING RADIATION

The Responsibilities of the Medical Profession

## UNITED NATIONS SCIENTIFIC COMMITTEE ON EFFECTS OF ATOMIC RADIATION

**P**UBLIC health problems created by the development of atomic energy caused the United Nations General Assembly to establish a Scientific Committee on the Effects of Atomic Radiation. One of the most urgent tasks of this Committee is to collect as much information as possible on the amount of radiation to which man is exposed today and on its effects. Because a substantial proportion of the total radiation received is due to diagnostic radiology and radiotherapy, the Committee considers it desirable to draw attention to information that has been obtained on this subject.

Modern medicine has contributed to the control of many diseases and has substantially prolonged the span of human life. These results have depended in part on the use of radiation in the detection, diagnosis and treatment of disease. It is desirable, however, to review objectively the possible present or future consequences of increased irradiation of populations which result from these medical applications.

It is now accepted that the irradiation of human beings and particularly of their germinal tissues has certain undesirable effects. While many of the somatic effects of radiation may be reversible, germinal irradiation normally has an irreversible and therefore cumulative effect. Any irradiation of the germinal tissues, however slight, thus involves genetic damage which may be small but is nevertheless real. For somatic effects there may be thresholds for any irreversible effects although if so these thresholds may well be low.

The radiation due to natural sources has been estimated to cause between 70 and 170 millirem (milli roentgen equivalent man) of irradiation to the gonads per annum in most parts of countries in which it has been studied although higher values are found locally in some areas. In addition the human race is

subjected to artificial radiation due to medical applications, to atomic industry and its effluents, and to the radioactive fallout from nuclear explosions.<sup>1</sup> The Committee is aware of the potential hazards that such radiation involves, and is collecting and examining information on these subjects. The amount of radiation received by the population for medical purposes is now, in certain countries, the main source of artificial radiation, and in Sweden and the United States is probably about equal to that from all natural sources. Moreover, since it is given on medical advice, the medical profession exercises responsibility in its use.

The Committee appreciates the importance and value of the correct medical use of radiation, both in the diagnosis of a large number of conditions and in the treatment of many such diseases as cancer, in the early mass detection of conditions such as pulmonary tuberculosis, and in the extension of medical knowledge. Moreover, it appreciates fully the contribution of the radiological profession, through the International Commission on Radiological Protection,<sup>2</sup> in recommending maximum permissible levels of irradiation. As regards those whose occupation exposes them to radiation, the establishment of these levels depends on the view that there are doses which, according to present knowledge, do not cause any appreciable body injury in the irradiated individual, and also on the consideration that the number of people concerned is sufficiently small for the genetic repercussions upon the population as a whole to be slight. Whenever exposure of the whole population is involved, however, it is considered prudent to limit the dose of radiation received by germinal tissue from all artificial sources to an amount of the order of that received from the natural background radiation.

*It appears most important, therefore, that medical irradiations of any form should be restricted to those which are of value and importance, either in investigation or in treatment, so that the irradiation of the population may be minimized without any impairment of the efficient medical use of radiation.* The Committee is consequently anxious to receive information through appropriate governmental channels as to the methods and the extent by which such economy in the medical use of radiation can be achieved, both by avoiding examinations which are not clearly indicated and by decreasing the exposure to radiation during examinations, particularly if the gonads, or the fetus during pregnancy, lie in the direct beam of radiation. It seeks, in particular, to obtain information as to the reduction in radiation of the population that might be achieved by improvements in instrument design, by fuller training of personnel, by local shield

# TREATMENT OF PARAPHIMOSIS

RICHARD W. CLIFTSOWAY *Captain, MC USA*

EVAN L. LEWIS *Lieutenant Colonel MC USA*

**P**ARAPHIMOSIS is the condition where a tight or inflamed foreskin is caught proximal to the glans penis and the patient cannot replace the foreskin in its normal position. This tight foreskin occludes circulation and causes swelling of the subcutaneous tissues between the glans and the constricting band. If this condition is prolonged, there may be tremendous swelling, gangrene of the constricting band, and eventually gangrene of the entire penis distal to the band. The treatment of paraphimosis outlined in the standard books of urology<sup>1-4</sup> are (1) hot applications and cleansing of the lesion, (2) manual reduction of the foreskin and, in case this is unsuccessful, (3) dorsal slit followed by circumcision after the dorsal slit heals and the inflammation and swelling subside. The first method is to be condemned for delaying definitive therapy. The second method should be tried and will be successful in the majority of early cases. It is the third method, dorsal slit, that we intend to discuss.

This method seems to involve an unduly long morbidity. Dorsal slit relieves the circulatory embarrassment caused by the constricting band, but the edema subsides only slowly. The method also leaves a wound, which theoretically should be allowed to heal prior to definitive therapy by circumcision. Ideally, the edema subsides, the wound heals, and the inflammation disappears so that circumcision can be performed in from 2 to 3 weeks. Circumcision produces another 7 to 10 day morbidity. By morbidity is meant not necessarily hospital time, but a period of incapacity due to pain and swelling. This unsatisfactory total morbidity of from 3 to 4 weeks is frequently markedly prolonged when the dorsal slit, which is made across edematous, anoxic tissue, becomes infected.

## CASE REPORT

A 21 year old corporal was transferred from a nearby dispensary to this hospital on 14 October 1953 with a marked paraphimosis and necrosis of the dorsal portion of the constricting band. This condition had been treated as balanitis for five days with antibiotics and soaks. Immediately on arrival the patient was taken to surgery where a dorsal

---

From Tokyo Army Hospital APO 500 San Francisco Calif. Dr Cliftsoway is now at 1235 Morro Street San Luis Obispo Calif.

slit was done. It was not until 27 October 13 days later that he was ready for circumcision. He was released 31 October. Total morbidity—22 days.

We could not see why immediate circumcision could not be done in those cases where dorsal slit had been indicated. This would eliminate the dorsal slit operation. Anesthesia would be required once rather than twice and the morbidity would be decreased by that long period between dorsal slit and circumcision. There seemed to be no greater possibility of infection of the circumcision wound than of the dorsal slit wound and with the use of prophylactic antibiotics the procedure seemed even more feasible. In reviewing the literature the only pertinent reference found was a description of immediate circumcision in 42 cases of infected phimosis. The author cited a marked improvement in results with "healing per primam" 9 cases, healing satisfactory 18 cases, some infection along suture line 11 cases, healing slow 4 cases. At the time antimicrobial therapy was limited to sulfanilamide, sulfapyridine and sulfathiazole given in very limited amounts.

Our method is to operate as soon as possible after the patient is first seen. The anesthetics used are Pentothal Sodium (brand of thiopental sodium) injected intravenously and nitrous oxide and oxygen by mask. Circumcision is done by the dorsal slit technique removing all the edematous foreskin in ulcerated area and grossly inflamed skin down to fairly normal skin on the penile shaft. Although the mucous membrane reflected from the glans is edematous and somewhat friable no difficulty has been encountered in the suturing when a No. 0 plain catgut continuous suture is used. A petrolatum impregnated gauze dressing is applied. This is removed completely on the second postoperative day. Five hundred milligrams of Terramycin (brand of oxytetracycline) is given four times daily for five days.

Since August 1953, we have performed immediate circumcision on 13 patients with paraphimosis for whom dorsal slit would usually be indicated. Elevation of this number showed ulceration and gangrene at the site of the constricting band. All incisions healed by primary intention and no patient had a morbidity or hospital stay longer than for the average circumcision. If anything the wounds healed faster and looked better than those of some patients who had had routine circumcisions without receiving antibiotics.

#### CASE REPORT

A 25 year-old corporal was transferred to this hospital on 15 September 1953 from a nearby United Nations dispensary. He had a history of "balanitis" for 5 days for which he had been treated with antibiotics and soaks with a gradual increase in swelling and pain (fig. 1). He

was found to have a marked paraphimosis with ulceration of the constricting band on the dorsum of the penis. The paraphimosis could not be manually reduced without severe pain. The patient was taken immediately to surgery where circumcision was done as previously described (fig 2). The patient made an uneven recovery and was returned to the referring unit on the fourth postoperative day (fig 3).

*Figure 1 Phimosis of 5 days duration with ulceration of the constricting band*

Because this method gave such uniformly good results, we recommend its use in all cases of paraphimosis which cannot be easily and painlessly reduced.

#### SUMMARY

Paraphimosis, if not adequately treated soon after it occurs, may produce a prolonged morbidity. In its early stages, it can be successfully treated by manually reducing the foreskin. When it has progressed to marked edema, ulceration or gangrene, and infection, operative intervention is required.

If a dorsal slit of the constricting band is allowed to heal before a circumcision is performed, an inordinately long morbidity may result. Thirteen patients with paraphimosis requiring operative intervention were treated by performing an immediate circumcision. With prophylactic antibiotic therapy the wound healed rapidly and morbidity was markedly reduced.

Immediate circumcision is recommended as a replacement for the dorsal slit procedure in the treatment of paraphimosis when manual reduction of the foreskin is impossible.

# CHLORPROMAZINE JAUNDICE

ROBERTO F. BENITEZ, *Lieutenant Colonel MC, USA*

THEODORE A. MERSCH, *Lieutenant Colonel MC, USA*

JOSEPH CASTAGNO, *Lieutenant Colonel MC, USA*

EDWIN M. GOYETTE, *Colonel MC, USA*

**C**HLORPROMAZINE, one of the recently discovered tranquilizing drugs, is in widespread use, especially for psychiatric patients. It has been used in Europe since 1951 and in America since 1954. The evidence gathered to date seems to indicate that these drugs will prove most useful in those patients for whom barbiturates were found to be effective in the past, and especially in outpatients.

An obstructive type of jaundice caused by this drug has been reported with increasing frequency in the recent literature. Clinically, it is important to distinguish this type of jaundice from others of obstructive type, as the condition may be erroneously attributed to some cause amenable to surgery and an unnecessary operation performed. In the following case the diagnosis was made clinically and confirmed by liver biopsy.

## CASE REPORT

A 28 year old white enlisted man with 10 years' service was hospitalized from 22 October to 2 November 1955 for depressive symptoms after two months in Germany. The history as obtained from his wife indicated that he "acted childlike just as a small boy would act." He had financial difficulties with his mother who demanded support from him. The patient was discharged on 2 November on a social service follow-up basis and on this day he was started on 25 mg of Thorazine (brand of chlorpromazine) three times per day. Depression recurred with anxiety and lack of confidence and he complained about failing his wife and children, inadequacy and an inability to "face things." On 17 November he took 3 Thorazine tablets, 1 aspirin and 2 teaspoons of elixir of phenobarbital sodium. He told his wife who took him to the dispensary. Because of language difficulty (the wife is Japanese), the German doctor sent the patient to a hospital as an attempted suicide.

Physical and neurologic examination was essentially negative. The patient appeared depressed, looked away and was passively uncooperative. He talked little and sighed often. His thoughts were poorly

---

From U. S. Army Hospital, Frankfurt APO 757 New York N. Y.

organized but not dissociated. There were no delusions or hallucinations and affect was generally appropriate.

Laboratory studies on 18 November showed a hemoglobin of 14.8 g/100 ml and a white blood cell count of 6500/ $\mu$ l with 59 per cent neutrophils, 25 per cent lymphocytes, 15 per cent eosinophils and 1 per cent basophils. The serologic test for syphilis was negative and the heterophile antibody titer was normal. Total cholesterol was 350 mg/100 ml esters 68 per cent of total. Liver function tests are shown in table 1. On 16 December the prothrombin time was 90 per cent of normal and on 6 January 1956 a roentgenogram of the abdomen was negative.

On 25 January hematocrit was 46 ml/100 ml, hemoglobin 15.8 g/100 ml, red blood cell count 6 040 000/ $\mu$ l and white blood cell count 5200/ $\mu$ l with 55 per cent neutrophils, 41 per cent lymphocytes, 2 per cent monocytes and 2 per cent eosinophils. Bleeding time was 2 $\frac{1}{2}$  minutes, coagulation time 12 $\frac{1}{2}$  minutes and sedimentation rate 25.

The patient was placed on a closed ward and given a regular diet and 0.2 gram of Amytal Sodium (brand of amobarbital sodium) before bedtime. The day after admission he noticed severe generalized itching and the following day his stools were light colored. His appetite was poor the first week and he was depressed and unsociable. He lost some weight after admission and appeared lethargic and disinterested. On 28 November he was placed on 0.75 mg of Serpasil (brand of reserpine) twice a day and moved to an open ward.

On 5 December scleral icterus was first noticed. The patient then stated that his urine had been dark since 10 November. Examination on 5 December revealed moderate icterus of the sclerae and skin, multiple excoriations of the skin due to scratching, and non-tender enlargement of the liver two fingerbreadths below the right costal margin. All medication was stopped and he was placed on modified bed rest on a high protein, high-carbohydrate, low-fat diet supplemented with hexavitamins. On 14 and 15 December he had diarrhea, five to six stools each day. There was little change in icterus and itching during the following six weeks and on 26 January biopsy of a specimen of the liver was performed.

The gross specimen was a threadlike fragment of mottled greenish-tan tissue approximately 3.5 cm in length. Microscopic examination revealed liver tissue in which the architecture was essentially unchanged. There was marked plugging of the hilar canaliculi by green bile thrombi, usually in the central portion of the lobules (fig. 1) and bile pigment in Kupfer's cells. The portal areas were not unusual. A few showed a sparse sprinkling with mononuclear cells. The bile ducts showed no dilatation or plugging. Within the lobules some individual cells showed degenerative changes with an orange or hyaline-like cytoplasm and pyknotic nuclei. In areas there was a slight variation in the

TABLE 1 Summary of liver function tests in patient with chlorpromazine jaundice

size and shape of the cells and nuclei. Bizarre multiple nuclei could be found in some cells (fig 2). A few usually single eosinophils could be seen.

These changes were interpreted as intrahepatic bile stasis compatible with so-called "chlorpromazine jaundice." The degenerative and regenerative changes suggested some degree of liver damage. However it could not be determined histologically whether this occurred before or after Thorazine therapy.

Figure 1 Central area of liver showing bile plugging of canaliculi and bile pigment in Kupfer's cells. (Hematoxylin-eosin stain  $\times 500$ )

Further questioning of the patient failed to elicit any history of previous hepatitis or liver disease. When evacuated to the zone of the interior three months after onset he was still jaundiced. The pruritus had diminished slightly in intensity since admission. The total serum bilirubin was still elevated. The only follow up we have in this case is a letter from the patient dated six weeks after evacuation in which he indicated he was feeling well. The jaundice was "almost clear" and the laboratory tests "almost normal."

Figure 2 Section of liver showing slight cellular edema, nuclear pleomorphism, hyperchromatism, and a multinucleated cell in the center of the field. (Hematoxylin-eosin stain  $\times 500$ )

### DISCUSSION

The general consensus of opinion is that jaundice constitutes an infrequent complication of chlorpromazine therapy. Various reports show an incidence varying from 1 to 5 per cent.<sup>1-3</sup> Zitt<sup>4</sup> stated that Megaphen (brand of chlorpromazine) has been used at the Frankfurt University Nervenklinik in about a thousand cases without a single case of jaundice occurring. Generally, European authors report a lower percentage of jaundice as a complication of chlorpromazine therapy. This aroused our curiosity and led us to believe that possibly there were some differences between various brands of chlorpromazine. However, on inquiring locally, we found that Megaphen, Largactil, and Thorazine are in fact all identical. The largest single series of cases in current psychiatric literature reporting complications in chlorpromazine therapy was a recent report by Denber and Bird.<sup>5</sup> In this series of 1,300 cases there were 18 cases (1.3 per cent) of jaundice reported, 8 developed within the first month of treatment with Thorazine, 9 within the second, and 1 in the third. After withdrawal of the drug, 15 of these 18 cases cleared in 7 days. Of the remaining 3 patients, 2 were suspected of having gallbladder disease, cholelithiasis

was found at operation in one of these two The jaundice apparently cleared in the other after 12 weeks

There are other complications in chlorpromazine therapy that occur with greater frequency than jaundice especially when large doses are given over a prolonged period of time In the series mentioned above a Parkinson like syndrome occurred in 85 cases (65 per cent) and a skin rash in 54 cases (4 per cent) Both of those complications also responded either to discontinuation of the drug or to appropriate specific therapy Other possible complications are lowering of blood pressure to dangerous levels and hyperpyrexia

The clinical features of chlorpromazine jaundice are usually as follows

1 It more commonly follows oral rather than parenteral administration Onset usually occurs a week or more after treatment in some cases from one day to two weeks after withdrawal One exception was Sussman and Sumner's<sup>6</sup> case, in which pruritus and jaundice appeared 2 and 12 days respectively, after a single dose of 50 mg of Thorazine

2 Grippelike symptoms with fever may occur

3 Abdominal distress usually without actual pain and change in bowel habits may occur at the onset

4 Occasionally there is nausea and vomiting

5 Jaundice appears several days later frequently accompanied by pruritus, dark urine and clay colored stools

6 The liver may be tender

7 The patient is seldom seriously ill

8 The jaundice lasts about three weeks In some cases it has persisted longer Azima and Ogle<sup>7</sup> reported one case where jaundice was still present seven months after onset

9 Biochemical tests suggest obstructive jaundice

10 Eosinophilia is seen in some cases Hartnett<sup>8</sup> reported one case with 58 per cent eosinophils at one time

11 Biopsy of the liver usually shows centrilobular bile stasis with or without inflammatory reaction Some pathologists<sup>9</sup> use this finding in differentiation from extrahepatic obstruction with the note of caution that this is not foolproof Others like Watson<sup>10</sup> believe that the lesions seen in cholangiolitic hepatitis and jaundice due to arsphenamine methyltestosterone or chlorpromazine are not distinctive

12 There is no residual hepatic damage after recovery. The last statement may be too optimistic. There are reports, such as that of Hartnott's case, in which there was evidence of residual liver damage (excess urobilinogen in the urine) six months after recovery. Some reports<sup>11</sup> point out that jaundice might be precipitated in patients with impaired liver function. It is also of interest that patients with previous liver disease show an increased responsiveness to chlorpromazine.<sup>12</sup>

Several fatal cases have been reported recently. Deschamps<sup>13</sup> case was a seriously ill patient who died on the fourth day of therapy for delirium tremens. However, he had severe cirrhosis of the liver. Boardman<sup>14</sup> described "toxic hepatitis" in his case. However, at the time there were three other cases in the hospital with infectious hepatitis. Tasker<sup>15</sup> reported a death in a patient who first exhibited jaundice and in whom the drug was continued until agranulocytosis developed before death. Hodges<sup>16</sup> patient also developed agranulocytosis before death. It differed in that only one 10 mg dose was given intramuscularly after an exploratory operation for jaundice. The patient had previously received 25 mg of chlorpromazine twice daily for 21 days. Agranulocytosis appeared a few days after operation. Seventeen fatal cases in 45 patients developing blood dyscrasias after the administration of chlorpromazine have been reported.<sup>17</sup>

The liver injury produced by chlorpromazine is similar to that caused by arsphenamine, thiouracil, methyltestosterone, and dinitrophenol. The various theories advanced to explain the changes favor the idea of direct toxic damage to cells. As a result of alterations in the cell membranes there is interference with hydration of the bile. Some authors<sup>18</sup> point to the edema of the central cells to explain the plugging of the canaliculi in this area, while the most peripheral areas are free of changes. This observation may explain why, in cases where a T tube is placed in the common duct, the bile drained is normal in volume and viscosity, since the bile secreted by the peripheral portion of the lobule is excreted without impediment.

There is much speculation as to whether the drug acts as a hepatotoxin or whether it is a matter of drug sensitization. In support of the latter theory is the delay in onset and the occurrence of granulocytopenia, agranulocytosis, and dermatitis in some cases. Dermatitis occurring in 13 of 425 nurses and 1 of 6 pharmacists handling chlorpromazine is reported.<sup>19</sup> Accelerated reactions have been explained on the basis of cross sensitivity, and it is pointed out<sup>4</sup> that chlorpromazine is closely related chemically to some commonly used antihistamines such as phenergan, which is a derivative of phenothiazine. Most authors emphasized that in several cases no jaundice had been observed on a s

trial with the drug. However, Sussman and Sumner's patient was given 38 mg of the drug orally seven months later. No jaundice appeared but the patient had epigastric distress, nausea and vomiting two hours later. The liver function tests were repeated and showed an elevation in the serum bilirubin and alkaline phosphatase.

In the management of this disorder a high caloric diet with added vitamins is recommended. Activity is restricted and the drug discontinued. Steroids are said to be of no value. Hydrocholeretic agents are suggested by some authors. A brief trial of corticotropin (ACTH) was ineffective in this case. The dosage of ACTH given was 25 mg intramuscularly daily for one week. It is realized that this dose was too small to be considered an adequate clinical trial. However, we were wary lest the patient's psychosis be aggravated by the hormone.

To date we have given Thorazine in varying doses to over 100 psychiatric patients. This is our first case of jaundice. Possible complications with any therapy must always be watched for; however, the possibility of this complication as yet does not preclude the further use of chlorpromazine in psychiatric patients.

### SUMMARY

A case of jaundice following administration of chlorpromazine is presented. Some of the clinical and pathologic features of this disease are discussed. The diagnosis can be made with a good history, appropriate liver function tests and biopsy of a specimen of the liver or cholangiography, and an unnecessary operation may be avoided.

## TRANQUILIZING DRUGS AND THE COMMUNITY

There are serious social implications we think in the widespread administration of Reserpine Chlorpromazine and the other tranquilizers Relaxation, within limits is all very well but it can be carried to a point at which individuals are removed from participation in society or at least made less aware than they ought to be of their surroundings A community most members of which were rendered wholly free from worry and tension could become a complacent community readily susceptible to the manipulation of a dictator Opium smoking relieves anxiety, too But it removes the smoker from reality People who mean to be self governing need to beware of too much tranquilization "

# IMPORTANCE OF FLEXION IN CERVICAL TRACTION FOR RADICULITIS

BENJAMIN L. CRUE, Jr. *Lieutenant Commander MC USN*

**H**ELPING the patient to obtain relief from pain in cervical radiculitis often seems a very difficult task. Cervical traction is one of the main forms of conservative treatment. However, if this traction is used incorrectly, the patient often gains no benefit, but may indeed be made more uncomfortable. In this syndrome the neck should be kept in flexion and not allowed to hyperextend.

The use of traction has long been a standard adjunct in the conservative management of the syndrome of herniations of the nucleus pulposus, both lumbar and cervical, by the orthopedist and the neurosurgeon. The routine use of bilateral leg traction for patients with lumbar disks has gradually been discarded in favor of earlier laminectomy, but the use of cervical traction seems ever to grow in popularity. Every physician has his own preference of helter type, weight, time schedule, length of trial, and concurrent use of physiotherapy, neck brace, or collar.<sup>1</sup> In the majority of conditions for which cervical traction is used almost any type of traction can be expected to give some degree of relief. In the tension syndromes, originally largely psychogenic, and even in the true organic cervical sprains and whiplash injuries, many types of traction will give varying relief. Often a trial and error method must be used. This is not true in cervical disk disease.

The literature contains many articles which discuss in detail cervical fractures or dislocations. There has been much less written concerning the technique of traction in the less acute or less severe conditions. Most head halters for cervical traction are constructed with a strap under the chin and a second strap behind the occiput. The straps may be of equal size, or the occipital strap may be smaller, mainly used to keep the larger strap under the chin from sliding forward. In either case, if traction is applied in a straight line with the long axis of the body most of the force is applied by the strap under the chin. This is especially true when overhead traction is applied with a heavy pull for a short

time, with the patient in a sitting position. This pull under the chin almost invariably lends to a considerable degree of extension of the neck. It should cause little wonder that this type of traction may result in little or no improvement, and may intensify the pain in those patients with true radiculitis resulting from encroachment on the foramina. One of the diagnostic signs of cervical radiculitis is radiating pain on hyperextension of the neck. Extreme flexion of the neck may also cause local pain due to tightness, but usually causes no radicular pain.

In the syndrome of herniated cervical disk there are two distinctly different general groups of cases. The acutely herniated nucleus pulposus, either protruded or extruded, with compression or irritation of a single nerve root, occurs in the cervical as well as in the lumbar area. If there are definite neurological signs of compression, prompt surgery is the treatment of choice for the herniated cervical disk. However, in the early or minimal case, or in the patient for whom surgery is otherwise contraindicated, cervical traction remains a factor in the conservative management.

This still leaves a large second group of patients with the so-called "hard disk" or "spurs" at the foramina. These patients are usually in the older age group. There is usually some degree of associated osteoarthritic change in the cervical spine. Often more than one root level is involved, and often the condition is bilateral. The usual picture is one of chronic recurrent radicular irritation with pain, but with only minimal neurologic evidence of nerve root compression. At times the disease may progress to the point where radical type surgery is necessary, but most observers agree that with the present surgical techniques, all attempts at conservative management should be exhausted first.

In the past five years the author has treated over twenty such patients with cervical disk syndromes for whom surgical intervention was not considered advisable. In the majority of these cases, cervical traction had previously been tried and either gave no significant relief or caused an exacerbation of radicular pain. With only one exception, all these patients obtained moderate to complete relief by reinstituting cervical traction, often over the patient's protest, and by flexing the neck 20° to 30°.

It is interesting to speculate why such neck flexion is of benefit. Examination of the cervical skeleton reveals that the spinal foramina are anterior to the midline of the spinal canal. But the fulcrum is not at the facets. The articulating surfaces slide upon one another, the most fixed point being anterior at the vertebral body. Thus, on flexing the cervical spine, the long diameters of the foramina should be increased and thus cause an over-all enlargement. That this is so can easily be demonstrated by roentgenography. The following roentgenograms are illustrative.

Figure 1 shows the roentgenographic appearance of the C5 C6 foramen in an oblique view in a 31 year old normal control with the neck in about ten degrees of extension with no traction. The

Figure 1 Roentgenogram (oblique view) showing C5 C6 foramen of 11.5 mm in length when the neck is extended 10° with no traction.

foramen measures 11.5 mm in the longitudinal axis. Without changing any factors except flexing the neck approximately twenty degrees the foramen (fig 2) now measures 13 mm. Figures 3 and 4 are similar oblique views of the C5 C6 foramen in a 35 year old master sergeant on active duty in the U S Army who had severe chronic cervical radiculitis with recurrent bilateral radicular pain for over nine years. Most of the pain had radiated into the thumb and index fingers. Neurologic examination revealed no atrophy, no weakness, no reflex changes and only minimal hypalgesia to pinprick over the C6 distribution on the right side. There were no long tract signs. Roentgenograms revealed arthritic changes in many of the cervical vertebra with narrowing of the C5 C6 interspace. The oblique views showed typical spurring at several of the foramina (fig 3). A myelogram revealed bilateral root cuff defects at C6 smaller cuff defects of C5 and C7 on the right, and midline bars at C4-C5 and C5 C6. Electromyography on the right revealed minimal lower motor neuron changes in the distribution of the C5 C6 and C7 roots. Hyperextension of the neck to 10° caused pain in both C6 root distributions. Figure 3 was taken

with the neck extended, and the C5 C6 foramen measured 8 mm. Figure 4 was then taken with the neck flexed  $20^{\circ}$ , and the foramen measured 10 mm. The patient was placed in cervical traction of 5 pounds with the neck flexed  $20^{\circ}$ , and the radicular pain subsided markedly within 24 hours.

Figure 2. Roentgenogram (oblique view) of same person as in figure 1 except that the neck has been flexed about  $20^{\circ}$ . The foramen now measures 13 mm.

There are many ways to obtain neck flexion while in cervical traction. I prefer to use a hand halter with equal straps. Then the pulley at the head of the bed is raised so that with the patient lying on his back the cord forms an angle of at least  $45^{\circ}$  (fig 5). This puts the largest vector of force into the strap behind the occiput and flexes the neck. The head is supported on a pillow or folded sheets. The patient is told that he should feel most of the pull at the occiput. If there is much pull under the chin, the apparatus should be rechecked. Occasionally a sponge rubber pad is used over the occiput to prevent pressure over the greater occipital nerves. Usually no pad is needed under the chin. A small weight (5 lb for women and small men, 7 lb for heavy males) over a longer period of time is preferred. Most patients soon obtain benefit from the traction and wear it gladly, and with no severe pull on the chin strap, they learn to sleep in the harness. Patients are usually allowed out of traction to eat, go to the

Figure 3 Roentgenogram (oblique view) showing a ring at the level of the cervical foramina and a C5-C6 foramen measuring 8 mm when the neck is hyperextended

Figure 4 Roentgenogram (oblique view) of same patient as in Figure 3 except that the neck has been flexed 20°. The foramen measures 10 mm

bathroom, or whenever the apparatus upsets them. If the pain is unilateral, turning the head slightly, usually away from the afflicted side, may increase the comfort obtained.

This traction technic is not original and is not presented as a "cure-all." Many patients have residual aches that do not subside or find that they need to continue the traction even after the acute episode of radiculitis subsides. Others find that as soon as they are ambulatory their attacks recur. It is believed, however,

Figure 5 Photograph showing traction apparatus arranged so that the cord forms an angle of about 45° at the pulley

that this type of cervical traction is superior to the usual traction in the long axis of the body in patients with true cervical radiculitis. This type traction with flexion has not been used, of course, in patients with large mid line lesions and signs of spinal cord involvement.

#### SUMMARY

Cervical traction is an important part of the conservative management of those patients with cervical radiculitis for whom surgery is not indicated. The usual methods of cervical traction, with the patient either sitting or in bed and with the pull in line

Figure 4 Roentgenogram (oblique view) of same patient as in figure 3 except that the neck has been flexed 20°. The foramen now measures 10 mm.

Figure 3 Roentgenogram (oblique view) showing spurring at the C5-C6 foramen and a C5-C6 foramen means several mm when the neck is hyperextended.

### LYMPHADENOPATHY AND FEVER

**Summary of Clinical History** A five month old white male infant was admitted to the hospital with initial symptoms of fever, lymphadenopathy, and irritability. He was born in Germany by a normal delivery, his birth weight was 7 lb, 11 oz. In the first weeks of life he had thrush and was treated with gentian violet. He gained weight steadily on breast feedings and remained well until the onset of his present illness. The parents and one sister, aged four, were living and well. The sister was stated to have had a calcified area in her chest, but a roentgenogram of her chest showed no calcification, and one of the mother's chest revealed normal findings. There was no tuberculosis, syphilis, rheumatic fever, allergic disorders, or diabetes in the family.

**First Hospitalization** When the patient was four and one half months old his mother noticed that he was irritable and feverish. He was examined by a physician, but no cause for the illness was found, and no treatment was given. His temperature continued as high as 105°F, and he was admitted to a hospital 10 days after onset of the illness.

Physical examination revealed cervical, slight axillary, and moderate inguinal lymphadenopathy. Except for a hot, dry skin

Col F Y Leaver MC USA Commanding Officer From the Laboratory Service Lt  
Col Roberto E Benitez MC USA Chief

with the long axis of the body, tend to cause neck extension and are not suitable in cervical radicular syndromes. Cervical traction with approximately twenty degrees of neck flexion seems to offer better results in this condition. This type of traction can easily be obtained with the patient lying in the supine position by merely raising the pulley on the usual traction apparatus.

## ETHICS AND THE SCIENTIFIC MAN

There are certain ethical considerations which are generally recognized among scientists. One of the most important is that in reporting an investigation the author is under an obligation to give due credit to previous work which he has drawn upon and to anyone who has assisted materially in the investigation. This elementary, unwritten rule is not always followed as scrupulously as it should be and of fenders ought to realize that increased credit in the eyes of the less informed readers is more than offset by the opprobrium accorded them by the few who know and whose opinion really matters. A common minor infringement that one hears is someone quoting another's ideas in conversation as though they were his own.

### LYMPHADENOPATHY AND FEVER

**Summary of Clinical History** A five-month old white male infant was admitted to the hospital with initial symptoms of fever, lymphadenopathy, and irritability. He was born in Germany by normal delivery, his birth weight was 7 lb, 11 oz. In the first year of life he had thrush and was treated with gentian violet. He gained weight steadily on breast feedings and remained well until the onset of his present illness. The parents and a sister, aged four, were living and well. The sister was stated to have had a calcified area in her chest, but a roentgenogram of her chest showed no calcification, and one of the mother's chests revealed normal findings. There was no tuberculosis, syphilis, rheumatic fever, allergic diseases, or diabetes in the family.

**First Hospitalization** When the patient was four and one-half months old his mother noticed that he was irritable and feverish. He was examined by a pediatrician, but no cause for the illness was found, and no treatment was given. His temperature continued as high as 105°F, and he was admitted to a hospital at the onset of the illness.

Physical examination revealed cervical lymphadenopathy and moderate inguinal lymphadenopathy. Except for a mild cough and

Col F Y Leary, MC, USA, Commanding Officer, U.S. Army Hospital, Frankfurt  
Col Roberto E. Benitez, MC, USA, Chief of Staff

and a temperature of 101°F physical findings were not otherwise remarkable

The red blood cells numbered 3 400 000/ $\mu$ l and the hemoglobin was 8.8 g/100 ml The white blood cell count was 52 850/ $\mu$ l with 54 per cent lymphocytes 2 per cent monocytes 1 per cent eosinophils, and 43 per cent neutrophils Repeated blood studies were essentially the same except that the red blood cell count fell to 2 500 000/ $\mu$ l The urine was normal Spinal puncture revealed clear spinal fluid with 31 cells (29 lymphocytes)/ $\mu$ l sugar was 74 mg/100 ml Roentgenograms of the chest revealed normal findings

On admission 7.83 mg (12 500 units) of potassium penicillin G every three hours and 0.12 gram of sulfadiazine every three hours were started The patient was hydrated and an attempt was made to control his temperature with baths and aspirin Nevertheless the temperature ranged from 101° to 105°F

**Second Hospitalization** After three days the patient was transferred to this hospital where it was noted that the liver was palpable four fingers breadth below the costal margin Other physical findings included moist rales throughout both lung fields, some generalized lymphadenopathy and marked pallor The spleen was not felt

Roentgenograms of the chest showed lobular prominence of the right hilar root consistent with lymphadenopathy, those of the abdomen showed a large soft-tissue tumor mass filling the left side from the subdiaphragmatic area to the iliac crest probably representing an enlarged spleen or kidney The skull and long bones appeared normal on roentgenograms

Therapy consisting of 200 mg of streptomycin sulfate orally every six hours was started in addition the child received 25 mg and 30 mg of streptomycin sulfate intrathecally There was no improvement and after four days streptomycin sulfate and penicillin were discontinued There was no change and 31.34 mg (50 000 units) of potassium penicillin G every three hours was started again Blood transfusions were also given

Blood studies showed a red blood cell count of 3 300 000/ $\mu$ l, hemoglobin was 10.5 g/100 ml The white blood cell count was 50 600/ $\mu$ l with 47 per cent neutrophils 51 per cent lymphocytes 1 per cent eosinophils and 1 per cent basophils A bone marrow examination revealed no evidence of leukemia The spinal fluid had normal concentrations of sugar and protein and produced no growth when cultured A sickle cell preparation and smears for malaria were negative A red cell fragility test had hemolysis beginning at 0.54 per cent and was complete at 0.28 per cent a

control began at 0.44 per cent and was complete at 0.28 per cent. The blood nonprotein nitrogen was 26 mg/100 ml, and total serum protein was 6.4 g/100 ml. The urine was normal on analysis. One blood culture was negative. After one week the patient was evacuated to a hospital in the United States.

### THIRD HOSPITALIZATION

**Physical Examination** The patient was a well developed, moderately well nourished, acutely ill infant with a temperature of 103°F. His breathing was rapid but not labored, and he had a frequent but not paroxysmal cough. His head measured 17 inches and the fontanelle was not tense. Pupils and fundi were normal. The tonsils were large but not infected. The ears and nose were normal. Many fine rales were heard throughout the lungs bilaterally. The heart was normal. The abdomen was slightly distended and tympanic. The spleen was large and firm, and extended halfway down to the pelvic brim. There was no cervical rigidity. There was generalized lymphadenopathy, and the epitrochlear and inguinal nodes were as large as almonds. Neurologic examination revealed no abnormalities.

**Laboratory Studies** Initially, the hemoglobin was 9.4 g/100 ml and the red blood cells numbered 2,600,000/ $\mu$ l. White blood cells were 24,150/ $\mu$ l, with 79 per cent neutrophils (15 per cent stab forms), 14 per cent lymphocytes, and 7 per cent monocytes. The blood smear revealed severe hypochromia with basophilic stippling. After blood transfusions, the red blood cell count was raised to 3,650,000/ $\mu$ l with 15 per cent reticulocytes, and the hemoglobin to 10.4 g/100 ml. The white blood cell count at this time reached a high of 33,300/ $\mu$ l, with 76 per cent neutrophils (30 per cent stab forms), 16 per cent lymphocytes, 6 per cent monocytes, and 2 per cent eosinophils. There was marked toxic granulation of the polymorphonuclear leukocytes. Platelets numbered 850,000/ $\mu$ l.

Two days before death the white blood cell count dropped to 2,650/ $\mu$ l, with 91 per cent lymphocytes, 5 per cent neutrophils, 3 per cent eosinophils, and 1 per cent monocytes, the red blood cells to 3,550,000/ $\mu$ l, the hemoglobin to 9.9 g/100 ml, and platelets to 199,350/ $\mu$ l. A Kohn test was negative. No malarial parasites were found on blood smears. The icteric index was 10, a red cell fragility test was normal, and agglutinations for Brucella were negative. The prothrombin time was 17 seconds with a control of 13 seconds. The urine was normal except for a few red blood cells seen in one specimen. The feces contained no parasites, ova, or occult blood, culture for typhoid and dysentery organisms was negative.

The spinal fluid was slightly cloudy, contained 13 cells (90 per cent lymphocytes)/ $\mu$ l, and had a slight increase in globulin.

Cultures of the spinal fluid and routine and acid fast stains of smears were negative. Throat culture showed *Micrococcus pyogenes* var *aureus*. Blood cultures were negative. *Streptococcus mitis*. Blood cultures were negative. Gastric washings contained no acid fast bacilli on smear or culture and no fungi on culture. Marrow from the right iliac crest showed erythropoiesis and a shift toward myelocytes in the myeloid elements. Early roentgenograms had revealed left pulmonary hilar adenopathy, but those taken on arrival at the last hospital showed a diffuse fine infiltrative process in both lung fields and the hilar adenopathy was less prominent. Roentgenograms of the abdomen showed a massively enlarged spleen that extended to the wing of the ilium. The liver was questionably enlarged. Roentgenograms of the skull were normal.

**Course in Hospital.** Penicillin and sulfadiazine therapy was started but it soon became apparent that these drugs were ineffective and they were discontinued. Regardless of medication the patient ran a high temperature for at least some part of each day throughout the entire course. He received many transfusions which had no dramatic effect. The need for frequent transfusions indicated that blood was being either lost or destroyed inasmuch as the reticulocyte count was high and the marrow was not hypoplastic. There was considerable productive cough and mucus was aspirated. Cyanosis was controlled with oxygen. The spleen progressively enlarged and reached the pelvic brim about 10 days after admission. Rales were always present in the lungs. The child was given 0.5 mg of aminopterin sodium daily for seven days without any helpful effect.

Several days before death the patient developed an erythematous rash mostly over the trunk and abdomen. In some areas it was petechial. Associated with this rash were a severe stomatitis and a generalized bleeding tendency. Vitamin K and liver extract therapy was begun. For the last three or four days prior to death the child was also jaundiced. The morning of the last day he appeared better. There was no longer bleeding from the mouth and mucous membranes. The rash had disappeared but the jaundice and fever were still present. The spleen was smaller and there was some regression of the lymphadenopathy. He died at 1305 hours that day about six weeks after the onset of illness.

#### DISCUSSION

**Doctor Knowles.** The problem is briefly that of a five month-old infant with fever, lymphadenopathy, a marked leukocytosis and a large mass in the left lower quadrant. This provokes an interesting differential

diagnosis encompassing most of the major groups of disease particularly one thinks of the devastating effects of systemic infection in this age group while being aware of the multiple complications of congenital abnormalities of the prognostically poor neoplasms and leukemias and of the often bizarre forms of metabolic disorders occurring in the young infant

The protocol first relates that a "disappearing calcific lesion" was present in roentgenograms of a sibling's chest. This is difficult to explain as the two diseases which might have first been suggested by opacities of the lung are tuberculosis and histoplasmosis both of which typically heal in the child by calcification, rather than by fibrosis as in the adult. We further have the findings of normal chest roentgenograms of the mother and a negative tuberculin test in the sibling. The further negative report of familial illness does not include the hemolytic diseases, and as there is a point in the case where congenital familial hemolytic anemia comes into the differential diagnosis, this might have been an important question to cover in the history.

The past history offers no clues except to state that the child was essentially well up until the onset of the present illness. The possibility that the infant's monilial infection occurred systemically is a remote one.

It may be assumed that the illness at its onset was somewhat insidious inasmuch as a physician neither recognized it to be serious nor offered treatment. By the time he was seen by the next doctor however he had developed a high temperature and appreciable lymphadenopathy. The blood cell count at this time was alarming with a marked leukocytosis but the differential is essentially normal for this age group. It was at this time that penicillin and sulfadiazine were started but apparently before obtaining important blood cultures. This may be why a diagnosis of septicemia could not be proved later. Even without meningeal signs, a lumbar puncture was wisely performed but the findings were essentially normal. If a diagnosis of miliary tuberculosis was considered at this time the normal sugar and protein determinations were important negatives. Usually in the meningeal form of the disease, the sugar is decreased below 50 mg/100 ml and the protein is increased above 50 mg/100 ml.

After enthusiastic hydration the patient was seen at the second hospital where in addition to previous findings, moist rales were heard in the chest and hilar prominence was noted radiographically. A roentgenogram of the abdomen apparently suggested further physical examination for a mass to the left side of the abdomen. It can be emphasized here that in examining a child's abdomen for the presence of a spleen, one starts at the iliac crest and works upward otherwise as in this infant the examiner will miss tremendously enlarged spleens and tumors, especially those associated with malaria, leukemia, Wilms's tumor and the reticuloendothelioses to name a few.

At this time an important negative finding of a normal skull and long bones was obtained. This helps to rule out an associated osteomyelitis secondary to sepsis and the Erlenmeyer flask bones of acute Gaucher's disease.

The attending physicians added streptomycin sulfate to the therapy and gave some of this medication intrathecally, presumably thinking of tuberculous meningitis. The spinal fluid sugar and protein however were normal.

Blood studies confirmed the leukocytosis with a slight increase in neutrophils. Tuberculous meningitis usually calls forth a monocytic response. Bone marrow examination failed to reveal leukemic cells as did the peripheral smears. This is strong evidence against the acute leukemias of childhood. A sickle cell preparation was also normal. It would seem unlikely that even if this white child were of Mediterranean descent and had the possibility of having a sickling trait, his present plight could be explained by such disease. Moreover the negative skull roentgenogram dispels this thought. Fragility tests were suggestive but were not confirmed later.

At a hospital in the United States rales were again noticed and persistently heard. This along with the appearance of a diffuse fine infiltrative process in the lungs strongly suggests the presence of bronchopneumonia. However these roentgenographic findings are often seen in the leukemias and other malignancies.

We are also told at this time that the child's fundi were negative. Again one of the reticuloendothelioses—Tay Sachs disease in which the cherry red macula is found—is ruled out.

Further physical findings only confirm previous examinations and laboratory examinations reveal that the leukocytosis shifted to younger cells of the granulocytic series. A poor prognostic sign is noted before death in the presence of marked toxic granulation of the neutrophils. We also note by the diminishing hemoglobin and increased icteric index that the red blood cells were being hemolyzed. The Kahn test and agglutinations for Brucella (and it is assumed for the other febrile agglutinins) were negative. If tuberculosis was still thought of the negative first and second strength tuberculin tests should have removed reasonable doubt as these tests are positive in approximately 92 and 99 per cent of active cases respectively. Blood cultures were again negative but in view of the antibiotics received it would be difficult to obtain positive results except with a tremendously overwhelming and continued bacteremia. Despite previous treatment the throat culture revealed a variety of organisms all cocci.

The hospital course was generally downhill. As an apparent desperate measure aminopterin sodium was given and probably accounted for the terminal agranulocytosis. Usually this drug is only given for

the acute leukemias, namely, the lymphogenous and myelogenous types. It does not seem to alter the course of the lymphosarcoma group.

Before summing up I should like to state that perhaps the major problem could have been solved by a lymph node biopsy. I would also like to have had an intravenous pyelogram of this patient to more completely delineate the abdominal mass and by so doing, help rule out a Wilms's tumor, a neuroblastoma, or other retroperitoneal mass.

The most frequent causes for splenomegaly and leukocytosis can be ruled out in this patient. (1) Mechanical causes such as rupture of the spleen may be discounted because of the length of the course and ancillary findings. (2) Infectious causes such as a septicemia resulting in a splenic abscess cannot be completely discounted. However, a bacteremia from typhoid, brucellosis, or tuberculosis usually does not call forth such a neutrophilia, a systemic fungus infection such as histoplasmosis is unlikely from the history and geography, and the protozoan infestations may likewise be excluded. (3) Hemie causes are unlikely in this patient. A hemolytic anemia is unlikely by nature of the course of the disease. Leukemia would appear to be a possibility in view of the treatment given the patient but is unlikely unless the results of further blood or bone marrow studies were withheld from the protocol. (4) Neoplastic causes such as a diffuse lymphosarcomatosis or primary splenic neoplasm are not ruled out, however, these would not provoke the leukocytosis found in this patient unless complicated by sepsis. Metabolic diseases such as the reticuloendothelioses are either not suggested by the history of this patient or were ruled out, except a fulminating Letterer-Siwe disease. This disease although usually associated with a neutropenia may well have been complicated by infection which would account for the neutrophilia.

Doctor Benitez: Doctor Spellman, perhaps you desire to discuss the roentgenographic findings.

Doctor Spellman: The lymphadenopathy or hilar enlargement noted on the chest films is apparently due to the same disease that caused the generalized lymphadenopathy. The most likely cause of the hilar adenopathy in this case would probably be tuberculosis, leukemia, or possibly Letterer-Siwe disease. The parenchymal infiltration was probably due to bronchopneumonia as rales were heard frequently on both sides of the chest. However, the infiltration possibly could be secondary to the original disease process. I do not remember having ever seen a case of Letterer-Siwe disease associated with parenchymal infiltration. Doctor Leaver, perhaps you have some remarks relative to Letterer-Siwe disease and parenchymal infiltration.

Doctor Leaver: In October 1952 Lackey, Leaver, and Farinaee<sup>1</sup> described for the first time two cases of eosinophilic granuloma of the

<sup>1</sup>Col. Charles E. Spellman, MC USA, Chief Radiology Service.

lungs along with an additional case of eosinophilic granuloma of bone with pulmonary findings. The radiologic picture is identical with that of Letterer-Siwe disease. Hand Schüller-Christian disease, Gaucher's disease, and other xanthomatoses consisting of a granulomatous infiltrate of nodular character with associated localized areas of emphysema and a slightly fibrotic background. The progress of these cases is very important as it is in this respect that the benign nature of eosinophilic granuloma is manifest as compared with the more malignant forms of the disease—that is, Letterer-Siwe disease and Hand Schüller-Christian disease.

**Dr Knowles diagnoses**

- 1 Bronchopneumonia
- 2 Septicemia complicating an underlying disease, either (a) neoplastic (lymphosarcomatosis) or (b) metabolic (Letterer-Siwe disease)

**Dr Spellman's diagnoses**

- 1 Tuberculosis
- 2 Leukemia
- 3 Letterer-Siwe disease
- 4 Bronchopneumonia

**PATHOLOGIC FINDINGS**

**Doctor Benitez:** This very intriguing case was seen at this hospital in 1948 and evacuated to Walter Reed Army Hospital where I had the opportunity to review the case and presented it originally at a clinicopathologic conference. The diagnosis entertained at this hospital was tuberculosis. At Walter Reed Army Hospital the diagnoses considered at first were histoplasmosis and leukemia. These were ruled out by various methods and finally after a node biopsy the true nature of the disease was determined.

At autopsy the salient features of the gross examination were as follows. The body was that of a well-developed, moderately well-nourished white male infant weighing 6,050 grams. The skin and sclerae were icteric. There were palpable lymph nodes in the neck, axillae, and groin. In the thorax the visceral and parietal pleurae were loosely adherent by fibrinous adhesions at the lower lobes. One lobe showed a hemorrhagic infarction. The liver weighed 375 grams, approximately twice the normal weight, and the spleen 110 grams, approximately six times the normal. The splenic capsule was opaque over the greater curvature. The mediastinal and retroperitoneal lymph nodes were small. In the mesentery they were larger, measuring up to 1 cm in diameter. The remainder of the gross examination was sketchy and no other findings of significance were noted.

On microscopic examination there was a striking proliferation of the reticuloendothelial elements (fig 1). This was noted particularly in the lymph nodes, spleen, liver, pleura, and adventitia of the stomach.

The predominant cells were nonlipid containing histiocytes often showing active phagocytosis of red blood cells. However in some of the mesenteric nodes some of these cells had the appearance of foam cells (fig. 2). In the serosa of the pleura and stomach the histiocytes were present in large numbers and showed a transition to fibroblasts. The pleura was thickened and thin interlacing collagen bundles were seen between the cells. There was also peribronchial infiltration with histiocytes and again the same fibrosis was noted in these areas. This was also noted in the spleen where the concentric layers of fibers and cells around the blood vessels in the malpighian corpuscles gave them

Figure 1 Lymph node showing marked proliferation of reticuloendothelial cells. These cells are pale and larger than the few lymphocytes seen in this field. (Hematoxylin eosin stain  $\times 250$ )

a granulomatous appearance (fig. 3). The sinusoids and the red pulp of the spleen were heavily infiltrated with histiocytes. Erythrophagocytosis was marked and considerable hemosiderin pigment was found within the cells. This was also found in the bone marrow and liver. In the latter the Kupffer's cells were prominent and laden with pigment. Many hepatic cells were also found to contain pigment. There was thickening of the leptomeninges with infiltration by histiocytes and mononuclear cells.

In many tissues other mononuclear cells were seen in a with the reticuloendothelial proliferation. Eosinophils we

small numbers in the lymph nodes and spleen. In the bone marrow in addition to the reticuloendothelial hyperplasia there was a marked increase in the number of eosinophils.

The intractable anemia can be explained on the basis of the marked erythrophagocytosis by the reticuloendothelial elements and the infiltration of the bone marrow. The blood destruction also explains the icterus noted clinically and the hemosiderosis noted histologically. The skin rash, petechiae and hemorrhages are not the type of skin lesions usually described in Letterer-Siwe disease but can be attributed to the aminopterin sodium. The drop in the white blood cell count can also be attributed to this drug.

Figure 2 Mesenteric lymph node with foamy histiocytes crowded in the peripheral sinus. (Hematoxylin eosin stain  $\times 500$ )

The entity represented by this case has been known as Letterer-Siwe disease for many years although in the past and even today it is being reported under various names. Other terms used are "nonlipoid histiocytosis," "noninfectious reticuloendotheliosis," et cetera. The reason for disagreement on nomenclature has been the varied clinical and histologic features as well as the failure to demonstrate a causative agent.

In recent years there has been a trend to relate this disease to Hand-Schüller-Christian disease and eosinophilic granuloma of bone. The former is classically a disease of infants usually characterized by

cranial defects, exophthalmos, and diabetes insipidus. The predominant cell in the lesions is a xanthoma cell rich in cholesterol. Eosinophilic granuloma is usually a solitary bone lesion of older children and occasionally of adults. The predominant cell is the eosinophil.

From 1937 to 1940 several European<sup>3, 4</sup> and American<sup>5</sup> authors pointed to the relationship between Letterer-Siwe disease and the Schüller-Christian syndrome. In 1942 Green and Farber<sup>6</sup> noted the relationship to eosinophilic granuloma of bone. In 1944 Jaffe and Lichtenstein<sup>7</sup> postulated that the various clinico-anatomic observations in these three diseases merely represent gradations in severity of the same

Figure 3. Fibrosis and reticuloendothelial proliferation in the spleen. (Hematoxylin-eosin stain  $\times 250$ )

disease process. Thus, on one hand Letterer-Siwe disease shows the most acute and severe manifestations; it is rapidly fatal and there is little or no lipid deposition in the reticuloendothelial cells. The Schüller-Christian syndrome represents a chronic form of the same disease with the presence of foam cells in the lesions that have not undergone fibrosis. Thirty per cent of these patients recover. Eosinophilic granuloma represents the most benign form with recovery usually occurring.

Lichtenstein<sup>7</sup> in 1953 reiterated the observations made in his first study. In this article he analyzed several recently reported cases of

these various syndromes and fit them into a pattern representing one disease which he named "Histiocytosis X" to emphasize the basic pathologic feature and the lack of a known cause. The classification he proposed is practical from the clinical and pathologic viewpoint. All the "atypical" cases of one or the other syndromes which have appeared in the literature can be easily placed in this classification. With this unity in mind it is easy to understand the transitions of one clinical and pathologic feature to another—e.g., an acute case of Letterer-Siwe disease going on to a chronic form of Schüller-Christian syndrome, eosinophilic granuloma presenting a chronic Schüller-Christian like picture and terminating with an acute course similar to Letterer-Siwe disease and various other possible combinations of clinicopathologic features.

No known cause for these three syndromes has ever been found. Infection has been considered but attempts to demonstrate pathogenic organisms and other infectious agents have been unsuccessful. The failure of antibiotic therapy in this case and the fruitless search for a pathogen illustrate this point. A disturbance of lipid metabolism has been considered and has now been generally discarded. Trauma has been incriminated in some cases especially in the single lesions of eosinophilic granuloma but most cases do not present a clear cut history of injury. Malignancy is difficult to ignore especially in the acute cases of the Letterer-Siwe type such as the present case. Other cases have shown leukemia like features and massive visceral infiltrations. Finally the relationship to age seems to direct attention to a possible endocrine imbalance. As Craig points out in the spectrum formed by the unified group it is noted that in the majority of cases the fatal cases have an age at onset of less than a year. If the visceral involvement is nonfatal the age at onset is somewhat later—a little over a year. In those with multiple bone involvement the age at onset is three years or more and finally when there are single bone lesions the age at onset may be around eight or nine years or even later. The occasional cases bridging the gap such as the reported cases of Letterer-Siwe disease in adults<sup>1,2</sup> are particularly thought provoking. Noteworthy in this case is the occurrence of foam cells, eosinophils and fibrosis.

### THE MENACE OF NODULAR GOITERS

How great is the menace of nodular goiters particularly single adenomas still remains a debated question. No doubt the majority of patients even if not treated will survive without malignant changes ever developing within the gland. Yet the high incidence of carcinoma reported by many writers, especially appearing later on in nodular goiter particularly of the single type must give us pause. We have seen so many patients whose histories indicate that they have had nodular goiters for years which could have been readily enucleated and who now come to us with extensive and frequently hopeless carcinomas that we are compelled to feel that a thyroidectomy should be carried out in all instances of adenomatous goiter.

## SERVICE ARTICLES

### PRESENT DAY MILITARY OBLIGATIONS

DANIEL C. ELKIN M. D.

**N**O President of the American College of Surgeons or in deed the head of any other responsible medical organization will have done his full duty today if he does not speak out soberly advisedly and with due consideration on another subject, the role and obligations of all physicians in a world that may not be at war but is surely not a world at peace. In the event of thermonuclear warfare and an attack upon the industrial cities of the country which make up the target areas there will be a flood of casualties over the target areas battle in the history of the world ever before produced. The surviving casualty load will far exceed the immediately available medical resources. The immediate problems but it will require the and thermal burns are surgical problems—all of us who survive—services not only of surviving surgeons—but it will require the but of others also to cope with the situation. Battlefield principles must be applied. Preferential care in the system of priorities must be given to those who can be returned to duty rather than to those who are close to death.

The surgical profession has a heavy responsibility in planning and training and indoctrination against a day of disaster. Preparations may be puny but they may turn the scale for or against national survival or destruction in an all-out war. If any of us are to survive, it will be because in this time of specious peace all of us have set our hands to the task while there is still time.

There is another point to be made in this connection. I think that we err greatly and are derelict in our duties those of us who stand in the kind of office in which by your graciousness I find myself tonight if we do not firmly and unequivocally take the position that the young man who now goes into medical practice must face and accept the almost inescapable fact that before he is free to follow his own desires there is every chance that he may be called upon to give his time and service to the Armed Forces of the country.

Extract from the Presidential Address to the American College of Surgeons delivered at the San Francisco Meeting, October 1956.  
Dr. Elkin is at Elkin Place, Lancaster, Ky.

This is the situation. Every 18 year old must register for military service. The prospective physician can request deferment while he finishes high school, while he completes his premedical work, while he is in medical school, while he serves his internship, and, perhaps, while he serves a year or more of residency. He will be granted these successive deferments without question if his grades and his performance warrant it. But, after he has been deferred for those nine years or more, there will come the almost inevitable day when he must enter some branch of service. I grant you that the situation as it exists is unfair and discriminatory. If the student desires to fulfill his military obligations when he is 18, and fulfills them then, it will profit him nothing when he has become a Doctor of Medicine. For all practical purposes he is in double jeopardy. He must still do service for two years as a medical officer. From that obligation there is little chance of escape.

Unfair? Yes. Wastage and inefficiency in the use of medical officers? Yes, there is undoubtedly some basis for this charge. But, I ask you, what are we going to do about it? The Act of Congress by which physicians must serve in the Armed Forces will expire in June 1957, but it will still remain the obligation of the Government to maintain a medical service with a balanced structure. The men in the service must be cared for in peacetime as well as in war. The Surgeons General of the Army, the Navy, and the Air Force are charged with these responsibilities. We of this College will be derelict in our own duties if we do not hold up their hands.

How best can we fulfill the obligations of the College in this regard? In two ways, I would say. First, we must take the position, automatically and without cavil, that as a matter of course every matriculating medical student must look forward to two years of service in the Armed Forces. Second, we must take our stand firmly against the cynical notion that is rather popular at this time, that these two years are a waste of time, almost a backward step in one's medical career. It is never a waste of time to serve one's country. I should like to see every instructor in every medical school devoting some of his teaching effort to refuting these notions and to emphasizing the concept that if these years are a waste of time, it is a reflection on the individual medical officer and on those who failed to prepare him for his military obligations rather than a reflection on the services. Medical schools must take cognizance of the world. This is a fundamental problem of orientation, and it is one to which I should like to make a constructive contribution.

There exists no vacuum in the medical school curriculum as I am well aware for courses in military medicine. There is no reason however why certain matters of military medicine cannot be integrated into existing courses of medicine and surgery. We made a serious mistake in World War II in that we failed to use the surgical lessons of World War I. It is sadly true that the lesson of history is that the lesson of history is never learned.

As a matter of fact there is a great deal in the story of surgery in World War II that is applicable to peacetime practice. Further more given the chance medical students show a surprising interest in that story. I have myself since the war devoted a good deal of time to recording my own surgical experiences in it and to hounding my confreres into reporting theirs. Some of these surgical histories are already available. Others will appear shortly. Still others are in preparation. You will find them interesting and profitable reading whether or not you went to the wars and if you will permit me the plug the Government Printing Office will be glad to sell them to you at a remarkably reasonable price.

---

### THE INCIDENCE OF ALLERGY

Allergy is a common condition. Less frequent probably than some enthusiastic practitioners would claim and more common than is realized by a considerable number of physicians. There may be many who disagree regarding the classification of some conditions as allergic but when the elimination of questioned conditions has been made by conservative men there still remains a hard core of approximately 10 per cent of the population who suffer from one or another condition unquestionably allergic.

# A PSYCHIATRIC STUDY OF A RETRAINING COMMAND

NATHAN SCHLESSINGER *Lieutenant MC USNR*  
DAVID BLAU *Lieutenant MC USNR*

**T**HE OPPORTUNITY to serve as a medical officer at a naval retraining command, which serves as a place of confinement for courts martial prisoners with minimum sentences of four months, is a unique experience for a psychiatrist. Most psychiatrists have had little contact with this type of work in an ordinary civilian or Navy practice. Stresses arise in confinement which are unparalleled in everyday life, and serious emotional disturbances are not uncommon.

From our experiences as psychiatrists attached to this retraining command, we derived certain attitudes and impressions that form the basis of this article. Although some of our observations may be specifically pertinent to this retraining command, we believe that our comments may have general bearing on all such commands operated by the Navy.

Five hundred consecutive new arrivals appearing between October 1955 and January 1956 were routinely screened with an extensive personal history questionnaire completed by the prisoner himself, and with a social history and service record review by the Navy Classification Specialist. After this information was collected, each of the prisoners was seen briefly in psychiatric interview, and an appropriate diagnosis and recommendation for restoration, clemency, or administrative discharge were made.

## CHARACTERISTICS OF PRISONERS

In brief, the average prisoner was young and had spent a relatively short time in the service. The majority had been awarded punitive discharges, and almost half the population were the product of broken homes (table 1). Many reported difficulties in school prior to entering the service, and a considerable number indicated a significant history of alcoholism. A large majority were confined for AWOL and desertion. Diagnostically, they fell into the category of severe character and behavior disorders.

---

From U S Naval Retraining Command U S Naval Base Portsmouth N H. Dr Schlessinger is now at 5327 South Dorchester Chicago 15 Ill.

Of the 500 prisoners studied 112 were being restored to duty. These men were compared with the over all group. The only significant differences occurred in the distribution of the ages and the psychiatric diagnoses of the men. The restorees tended to be

Fifty-one per cent reported trouble in school including as a major and difficulties with the teachers or other pupils.

Only the most serious offenses of each man were considered seriously serious violations of the Uniform Code of Military Justice and were counted separately. Offenses like breaking restriction and failure to follow orders were omitted.

\* Twelve of this group were recommended for admission to the military.

\*\* Only serious offenses were included. The rest of the offenses were minor offenses like entering, auto theft and larceny.

This diagnosis was used to describe men who were not in the usual difficulties of adolescence and might be expected to have serious difficulties in the future as they resolve their adolescence problems.

younger (78 per cent were under 21 years of age) and were considered to fall within the normal range for the areas compared, the two groups were not significantly different.

#### DISPOSITION OF PFTC, ET

A great number of the retrainees were men who were marginal manpower who could not do the work of the beds, do inferior work, and get into the firm and the other studies<sup>1-3</sup> have described the problems of the men in the service in attempting to do the work of the beds. It was not surprising that the retrainees were in disciplinary trouble and in confinement.

It was recommended that about 10 per cent of the restorees be discharged from the service. This figure was modest in view of the number of psychiatrically handicapped men interviewed. If the policy regarding administrative separation would have permitted it a larger number would have been recommended.

Many rational arguments were raised to oppose discharging men administratively. Some considered an undesirable discharge to be more punitive than a bad conduct or dishonorable discharge. Others objected on the grounds that an administrative discharge permitted men to escape from a contracted agreement to serve their country and to obtain the benefits of an honorable discharge. While it was true that these men would not serve out their enlistment if they were separated, it appeared likely that many of them would fail to do so after they were restored to duty. In addition, many of those men would be ultimately faced with further confinement and finally a punitive discharge.

We noted a tendency on the part of staff personnel to deal harshly with provocative prisoners who loudly proclaimed that they were not motivated for further service and were interested in being discharged. Such demonstrations frequently resulted in a prisoner being restored to duty as a form of further punishment. It was difficult for staff personnel to understand that such antagonistic behavior was part of the pathologic personality disorder of the inmate.

Duty personnel at retraining commands are concerned primarily with the problem of restoring men to duty. They are concerned about the number of prisoners who can be restored and use this number as a sign of the success or failure of their mission. Unfortunately, this is an unrealistic goal from a psychiatric view point. Many of the prisoners are suffering from serious personality disorders, to ask such people to adjust to military life successfully is similar to requiring men crippled by heart disease to run daily obstacle courses. Until recent times even among psychiatrists there was hesitation in recognizing that character and behavior disorders represent serious emotional difficulty. It was therefore understandable that duty personnel should feel that "acting out" could be readily controlled by conscious means.

Retraining commands are fortunate in being adequately staffed with personnel who can carry out the entire process of administrative separation. The presence of such experts as the legal officer, psychiatrist, psychologist, Red Cross representative and administrative personnel affords an ample opportunity of obtaining a broad picture of the inmate's personality and type of performance before confinement. The work supervisors and other duty personnel provide a picture of the adjustment in confinement. This careful screening and evaluation of each case should prevent the unnecessary separation of personnel who might be of value to the service.

It is understood that the criteria for administrative separation must vary with the manpower needs of the service. In time of peace, when the selection criteria for entrance into the service are relatively high, administrative separation might well be used more frequently throughout the service. Certainly in dealing with serious character and behavior disorders it would be well to consider greater use of this kind of action in the future.

### EFFECTS OF CONFINEMENT

Confinement provides a repressive environment in which the prisoners have lost their primary external objects for psychosexual gratification. Opportunities for using the familiar technique of acting out, so commonly employed by these men to handle their problems, are of necessity diminished by this repressive atmosphere. In spite of the external controls, however, some of the men continued to act out in confinement and became disciplinary problems. In general, these men had difficulty in controlling impulsive sexual and aggressive behavior. Some of the men in confinement experienced considerable internal anxiety, but usually there was an admixture of acting out and internally experienced anxiety.

Depressive reactions in confinement occurred rather infrequently and were hardly ever of serious proportions. Psychotic reactions in confinement were also observed infrequently. As a general rule, those prisoners who became psychotic in confinement rapidly recovered when they were removed from confinement and placed in a hospital situation. It was our feeling that recovery occurred because a specific kind of stress, namely, confinement, was removed. We are aware that some people would consider the possibility that those prisoners exhibiting psychotic symptoms might be malingering, but usually the ones who did develop psychotic reactions were described as either "borderline psychotics" or "prepsychotics" in their initial screening interview. The most typical psychotic reaction seen was that of paranoid schizophrenia.

Anxiety reactions frequently appeared a few weeks before a prisoner's release from confinement and were noted more often in those men who were receiving punitive discharges. Usually these feelings were related to the men's fear of losing control of impulses upon leaving confinement, as well as to the realistic problems confronting them in regard to their punitive discharges. Most of the prisoners expressed concern about obtaining a job, and many were afraid to face their families. It was often noted that they submitted requests to see the psychiatrist and complained of generalized nervousness, insomnia, aggressive impulses toward duty personnel, or a desire to change their living quarters. Such requests usually indicated mounting internal anxiety, which was frequently followed by acting out if the requests were not immediately handled.

The large majority of prisoners in confinement do not experience pathologic anxiety reactions nor do they become disciplinary problems as a result of their acting out. Many of the men react with an acceptance of the confinement situation. Confinement itself tends to protect people from their own impulses as well as to provide for their dependent needs. In addition the prisoners are provided with a target namely the duty personnel, for covert expressions of hostility. There is a considerable amount of group support among prisoners that enables the majority to remain out of disciplinary trouble.

The problem of malingering becomes extremely important when the prisoner is referred for psychiatric evaluation as the result of disciplinary difficulties. It is always difficult to separate the conscious motivation and desires of the prisoner from his unconscious problems. Disciplinary difficulties frequently are manifestations of increasing tensions arising as the result of the need to control forbidden impulses. It often is difficult for custodial personnel, who have been dealing with these men as conscious and willful individuals to realize that they have been acting out their unconscious emotional problems and are suddenly sick enough to require psychiatric attention. In general although malingering often has the outward appearance of a dramatic conscious attempt to avoid responsibility it is usually associated with serious unconscious emotional problems. As a result of the lack of awareness on the part of duty personnel men with psychiatric problems were often viewed as deliberately provocative and threatening and were usually handled in a repressive fashion.

We decided to study those men who were involved in disciplinary action of a serious nature and try to determine whether men with certain types of character disorders were more prone to cause trouble in confinement. Table 2 compares the psychiatric diagnoses of 100 men who had been reported for disobedience of orders at the retraining command with the diagnoses of the 500 men catalogued in table 1. The latter group provides a picture of the percentage of various character disorders scattered throughout the institution. The offense of disobedience was selected because it usually represents an outright refusal to co operate with authority figures.

Table 2 shows that men diagnosed as having passive aggressive reaction emotional instability reaction and antisocial personality were more frequently reported for disobedience than one would expect from their normal percentage in the population. It was also significant that all of the men who became psychotic in the institution were reported for disobedience.

Another interesting group made up of those men who were not reported for disobedience as frequently as one might predict from their distribution in the population were those diagnosed as

TABLE 2 *Psychiatric diagnoses of 100 men reported for disobedience during confinement compared with those of the total group studied*

Diagnosis	Reported for disobedience (per cent)	Total group studied (per cent)
Passive-aggressive reaction	32	25
Emotional instability reaction	25	18
Immaturity reaction (not further classified)	9	18
Inadequate personality	8	7
Antisocial personality	8	22
Schizophrenic reaction (not elsewhere classified)	3	<1
Passive dependency reaction	2	8
Schizoid personality	1	14
Sexual deviation (homosexuality)	1	1
Aggressive reaction	1	<1
Addiction (drug)	1	<1
Normal range	9	12.5

having either immaturity reaction (not further classified) or passive dependency reaction. One possible explanation for this might be that these two groups were composed of dependent men who received a great deal of gratification in confinement by having their oral needs satisfied and therefore did not have to resort to further acting out.

#### PRESENT PROGRAM

Rehabilitation efforts are difficult when men being prepared for return to duty after confinement are subjected to the same physical and disciplinary environment during confinement as those who will be returned to civilian life with punitive discharges. There has been some recognition of this problem at this retraining command, where a physically separate unit (Camp Langdon) was established. This unit functions specifically for the purpose of providing retrainees with an atmosphere approaching normal service life, and prepares them to return to the duties expected of them. Men with punitive discharges are retained in a closely supervised institution and undergo a completely different experience.

It is our opinion that, even though the two groups are structurally similar, their separation is necessary. It is that those men who are being returned to duty be prepared

chi

The large majority of prisoners in confinement do not have pathologic anxiety reactions nor do they have secondary problems as a result of their acting out. Many react with an acceptance of the confinement situation. The environment itself tends to protect people from their own weaknesses as well as to provide for their dependent needs. In general, prisoners are provided with a target, namely the guard, for covert expressions of hostility. There is a constant need for group support among prisoners that enables them to remain out of disciplinary trouble.

The problem of malingering becomes extremely acute when the prisoner is referred for psychiatric evaluation because of disciplinary difficulties. It is always difficult to distinguish between conscious motivation and desires of the prisoner and unconscious problems. Disciplinary difficulties are often manifestations of increasing tensions arising as the prisoner attempts to control forbidden impulses. It often is the job of the personnel who have been dealing with these prisoners to help them and willful individuals to realize that their unconscious emotional problems are serious enough to require psychiatric attention. Malingering often has the outward appearance of a conscious attempt to avoid responsibility with serious unconscious emotional problems. Lack of awareness on the part of disciplinary difficulties was often viewed as a psychiatric problem and were often viewed as threatening and were usually handled as such.

We decided to study those men who had a disciplinary action of a serious nature with certain types of character traits that cause trouble in confinement. The diagnoses of 100 men who were referred to the orders at the retraining center are catalogued in table 1. The percentage of various types of character traits in the institution. The cause of the trouble usually referred to by the authority figures.

Table 2 shows the reaction, emotional stability, and the type of behavior that would expect to be seen in the institution was also the most common.

An analysis of the reported behavior and their distribution.

# EXPERIENCES IN PROVIDING SALAD VEGETABLES TO AMERICAN FORCES IN JAPAN

LYMAN P. FRICK Lieutenant Colonel MSC, USA

RALPH O. ANSLOW Lieutenant Colonel VC, USA

IT IS probably not generally realized that providing green vegetables in the diet of troops can become an important military problem. A salad of lettuce, tomatoes, green peppers, carrots, and green onions mixed with a savory dressing is as great a morale factor as fresh milk, meat, and ice cream. United States servicemen become accustomed to eating fresh raw vegetables in their homes before they enter military service and they expect to see these foods regularly wherever their tours of duty take them.

The problem of supplying fresh vegetables to troops in the Far East Command has been complicated by several factors. Ordinarily, fresh vegetables grow profusely throughout Japan, Korea, and the Ryukus Islands during the proper seasons. Nothing would seem more natural than to be served these foods in troop messes and clubs except that nearly all fresh vegetables grown in the Orient are potentially contaminated, due to the use of night soil (human excreta) as fertilizer. This is one phase of orientation that most troops remember, at least in part, although many persons may later become careless in their off post eating habits.

Night-soil fertilization has been the prime concern. Intestinal parasitism and other enteric infections that may be transmitted by contaminated foods are common in the Far East, and surveys of the Japanese civilian population beginning in late 1945 indicated that appreciable increases in the incidence of some of these infections had occurred during the war years. As a result of the

shortage of medicines and physicians and concomitant curtailment of health programs during World War II, the occurrence of ascariasis, for example, had increased from a prewar average incidence of about 36 per cent to nearly 80 per cent.<sup>1</sup> Inasmuch as almost all repatriated Japanese troops and laborers from the islands of the Pacific and the Asiatic mainland were infected with some type of intestinal parasite, their return undoubtedly brought to the home islands many amebic carriers.

During the early occupation years the policy of American authorities was to take as little food as possible from the then meager resources of the Japanese. To complicate the problem further, water supply and housing were in a chaotic state and engrossment with general sanitation left a low priority for laboratory or field studies to determine the safety of local foods. All of these factors precluded extensive purchases of fresh produce by the military for troops in the Far East Command.

The problem of supplying fresh vegetables to troops in the Far East has had to be handled differently at different times. The purpose of this report is to survey the methods whereby these foods were obtained prior to 1955 and thereafter, and to review medical and laboratory data that might affect vegetable procurement.

#### PROCUREMENT OF VEGETABLES PRIOR TO 1955

Between the end of 1945 and early 1955 the only officially approved sources of vegetables, and in particular salad vegetables, for general troop use and commissaries were two hydroponic farms in Japan and produce from the United States. Quantities were constantly limited by the high cost of establishing additional hydroponic farms and the shortage of refrigerated transoceanic shipping space. An additional limitation was the short storage life of highly perishable items when imported from the United States. As an example, a considerable proportion of all tomatoes was lost due to spoilage even when the fruit was picked green and shipped under refrigeration. Additional spoilage occurred during transshipment to Korea. These conditions continued until early 1955.

During the same period, eating establishments operated by clubs, post exchanges, and approved Japanese hotels and restaurants served fresh vegetable salads throughout the year. Eating places operated by the military services were authorized to purchase many types of local produce on a warranty basis. It was required that vegetables be grown in chemically fertilized soils, or on Japanese hydroponic farms using only chemical fertilizers. Army Veterinary Corps inspections were made on this produce at wholesale warehouses or at the ultimate destination, but often

The problem of supplying fresh vegetables to troops in the Far East has had to be handled differently at different times. The purpose of this report is to survey the methods whereby these foods were obtained prior to 1955 and thereafter, and to review medical and laboratory data that might affect vegetable procurement.

#### PROCUREMENT OF VEGETABLES PRIOR TO 1955

Between the end of 1945 and early 1955 the only officially approved sources of vegetables, and in particular salad vegetables, for general troop use and commissaries were two hydroponic farms in Japan and produce from the United States. Quantities were constantly limited by the high cost of establishing additional hydroponic farms and the shortage of refrigerated transoceanic shipping space. An additional limitation was the short storage life of highly perishable items when imported from the United States. As an example, a considerable proportion of all tomatoes was lost due to spoilage even when the fruit was picked green and shipped under refrigeration. Additional spoilage occurred during transshipment to Korea. These conditions continued until early 1955.

During the same period, eating establishments, canteens, clubs, post exchanges and approved Japanese homes and restaurants served fresh vegetables obtained throughout the year. Eating places operated by the military service were authorized to purchase many types of local produce on a warranty basis. It was required that vegetables be grown in chemically fertilized soils, or on Japanese hydroponic farms using only chemical fertilizers. Army Veterinary Corps inspections were made on this produce at wholesale warehouses or at the ultimate destination, but often

little or no knowledge of the real origin of the vegetables was possible. Salad vegetables purchased under warranties were not authorized for use in troop messes or commissaries.

Troop messes in Japan and Korea have always served nutritious meals. This was true even during the most severe battle conditions of the Korean campaign. However, fresh vegetables often were unavailable in some areas for days or weeks, particularly during the nongrowing season when all vegetables came from the United States.

### PROCUREMENT ON A TRI SERVICE BASIS

By 1952 or 1953 vegetable production in Japan and Okinawa had recovered to the point where actual surpluses developed in Japan and relatively large purchases could be made without adverse effects on the Japanese market. If safe sources for vegetables could be established, troops could be supplied more liberally and at a great saving. The main problem, however, lay in developing these safe sources. Chemical fertilization seemed to be an obvious requisite. Rudolf Falk and Ragotzke<sup>1</sup> in an article published in 1951 had concluded that vegetables grown under conditions of surface sowage contamination showed no higher coliform contamination than those grown on normally farmed soils. Inasmuch as this study had been made in the United States it might not be entirely applicable to the situation in the Far East, especially in view of the exceedingly common occurrence of gastro-intestinal infections in the latter area.

It could be assumed that nearly all vegetables are grown in the Far East under conditions of night-soil fertilization and there is a mass of evidence to incriminate this practice in the transmission of enteric infections in areas of high endemicity. Therefore indiscriminate purchases of salad vegetables were not deemed advisable. Furthermore, nearly all arable soil in Japan was probably already contaminated with enteric organisms several of which are known to persist in soils for relatively long periods. Such soils could be potentially hazardous even if chemical fertilizers were used. Hence it was evident that if adequate supplies of vegetables, especially salad vegetables, were to be procured locally, principal consideration had to be given to establishing appropriate standards for their production and purchase.

As a result of a series of meetings attended by representatives of the Army, Navy, and Air Force, a tri service directive<sup>2</sup> was published in late 1954. This publication marked the first attempt in this theater to obtain uniformity between the three services in policies governing the procurement of local foods. The directive assigned central control of approved sources of foods to the veterinary branch of the Surgeon's Office, U S Army Forces,

Far East, 8th Army (Rear), and classified the types of vegetables that could be purchased without reference to approval of source and those that could be obtained only from approved sources. In addition, the directive established minimum sanitary requirements for the production, harvesting, processing, and delivery of salad vegetables. It was specified that growing plots had to be so located that they would not receive drainage from adjacent areas where night-soil fertilization was practiced. Growers were required to furnish a warranty that chemical fertilization had been practiced exclusively for at least four months prior to approval and would be continued for the duration of their contracts. Processing of vegetables on farms was prohibited; instead, growers were required to deliver their produce as harvested to processing sheds. Operators of these were required to comply with certain standards of sanitation, and were permitted only to process vegetables from approved farms. It was also specified that produce had to be delivered in clean, covered vehicles, and use of these for transporting contaminated materials was prohibited.

Japanese farms consist of a number of plots which may range in size from about 100 square feet to a maximum of approximately 6,000 square feet. Farmers living in close proximity organize into co-operatives and elect a supervisor to assist members in production and marketing. Action leading to approval or disapproval of a farm area ordinarily proceeds somewhat as follows. The request for approval is made by the co-operative to a Quartermaster Corps purchasing officer. After receipt, the request is forwarded to a veterinary inspector who travels to the area, performs an overall appraisal, and selects plots from which soil samples are collected for laboratory examination. Samples are collected from at least 20 per cent of the plots and from at least five points within each selected plot. Soil from the surface of an area of from 1 to 2 square feet is lightly scraped into a sterile wax paper lined paper bag with a sterile tongue depressor and transmitted to the 406th Medical General Laboratory where it is examined for human helminth ova and enteric bacteria. Sixty per cent of soil samples are required to be free from *Escherichia coli* and viable parasite ova. After inspection and laboratory examinations have been accomplished the inspector makes appropriate recommendations to the approving authority. If approval is given, a contract is made for the purchase of a quantity of vegetables, this quantity is based on a reasonable estimate of the production of the farms in the co-operative. Periodically during the term of the contract samples of a vendor's produce are drawn for laboratory examination. No more than 10 per cent of such samples can be contaminated by either *Esch. coli* or parasitic ova. This figure has never yet been reached.

The response of local producers to the program was excellent and the program progressed so successfully that by the end of the first growing season (fall of 1955) it was possible to obtain practically all needs of this theater for salad vegetables from local sources and at competitive prices. Since that time it has been required that all purchases be made from approved sources. In order to ensure an uninterrupted supply of tomatoes, cucumbers and green peppers at the start of the program those not obtainable from approved sources continued to be obtained under the warrant system. This authorization has been greatly reduced with a concomitant reduction in subsistence costs. One Quarter master Corps hydroponic farm has been scheduled for shutdown as a result of the success of the program. This farm had proved its value although it was an expensive source of vegetables. The program has also been well received by the military public. It was required however, that military facilities serving or selling locally procured food indicate these items on menus and placards.

#### FACTORS AFFECTING USE OF LOCALLY PROCURED PRODUCE

The Army Medical Service in the Far East was eager to increase the fresh components of the ration and to help in reducing ration costs by allowing the purchase of as many fresh vegetables and fruits as possible. However in recommending the use of local produce it had to consider that (1) there was a plethora of gastrointestinal infections in the Far East which possibly were associated with fresh vegetables and (2) the occurrence of such infections in American troops had been held to favorably low levels.

Many extensive surveys of the bacteriologic and parasitologic causes of intestinal diseases have been made in Japan particularly since 1945. These studies have been made by many groups of American investigators among troops and their dependents and among Japanese employees. Other special studies have been made on specific diseases in co operation with Japanese medical authorities. In addition the Japanese maintain extensive public health records which also include occurrence of gastro-intestinal diseases.

In table 1 data on the occurrence of ascariasis among the Japanese civilian population have been summarized for the years between 1930 and 1954. These data were obtained from Japanese public health records and include examinations of school children and government and industrial workers throughout Japan. There has been gradual improvement since 1946 but infection rates are still high by western standards.

TABLE I Occurrence of ascariasis in Japan between 1930 and 1954

Year	Persons examined	Percent positive
1930	516 986	50 6
1935	609 331	42 0
1940	593 759	37 2
1945	413 241	54 8
1946	821 765	67 2
1947	2 055 274	65 2
1948	3 334 597	62 9
1949	5 599 078	62 5
1950	7 220 649	59 6
1951	6 552 430	55 1
1952	6 191 607	48 3
1953	7 707,763	43 2
1954	8 019 238	38 0

Data from Japanese public health reports

Other Japanese reports show that diarrhea, enteritis, and "ulceration of the intestine" have been leading causes of death in Japan since 1900, the rate per 100,000 for that year being 130.7 for the group. In 1954 the rate was reduced to 38.9, however, in the years between 1920 and 1932 the rate was never lower than 200. No records were kept for the years 1943 through 1946, but the rates were undoubtedly high. Deaths from these causes ranked eighth in 1954, the rate being 38.9 per 100,000 population, or about the same as deaths from accidents (including motor vehicle accidents) which had a rate of 39. Gastroenteritis and colitis (except ulcerative colitis in children age four weeks and over) were the main causes of death in children one to four years of age in the period 1950 to 1954. During the same period, dysentery was the second principal cause of death in the same age group. Those reports give some indication of the problems experienced by the Japanese with intestinal diseases.

The U. S. Army's 406th Medical General Laboratory has conducted many studies on the incidence of helminthic and protozoan infections in the Japanese civilian population. A comprehensive report published in 1951<sup>4</sup> on representative population groups in all four main Japanese islands showed that ascariasis incidence was lowest (44 per cent) in the mountain areas of Hokkaido, and highest in the agricultural areas of Shikoku (91 per cent), Kyushu (92 per cent), Central Honshu (89 per cent), and Hokkaido (93 per cent). The same report noted that marked variations occurred in the incidence of amebiasis, with the lowest and highest indices occurring in Hokkaido (2.9 per cent and 26.2 per cent). The overall average for Japan in 1951 was estimated to be about 7.5 per

cent with cities having a lower rate than farm areas. Later this figure was revised upward to about 12 per cent.

By way of contrast there has apparently been little change in the occurrence of intestinal parasitic infections in American military personnel and their dependents in Japan since 1946. Data on 3 518 American personnel and 1 159 Japanese employees of U S Forces summarized in table 2 are representative and are useful in determining the basic levels of infection. Practically all of the Americans were dispensary patients from the Tokyo area and presumably had complaints possibly attributable to parasitic infections. The Japanese usually were young adults and assumed to be in good physical condition.

TABLE 2 Occurrence of parasitic infections in American military personnel and dependents and among civilian Japanese civil an personnel (Tokyo Japan, January to December 1954)

	Americans		Japanese	
	Number	Per cent	Number	Per cent
Persons examined	3 418		1 159	
Positive for parasites	751	22.0	649	56.0
Helminth infections	217	6.3	249	21.5
Ascaris lumbricoidea	91	2.7	231	19.9
Trichuris trichiura	60	1.8	68	5.9
Hookworm	12	0.4	169	14.6
Trichostrongylus sp.	36	1.1	4	0.3
Enterobius vermicularis	12	0.3	3	0.3
Strongyloides stercoralis	12	0.3	10	0.9
Others				
Protozoan infections	71	2.1	36	3.1
Entamoeba histolytica	149	4.4	120	10.4
Entamoeba coli	180	5.3	137	11.8
Endolimax nana	91	2.7	50	4.3
Giardia lamblia	29	0.8	3	0.3
Others (known nonpathogenic)				

From Personal Report 406th Medical General Laboratory 1954  
 Not included: a total number of infections because all patients prepared were not used in all instances.

A study of intestinal parasitism among 4 438 food handlers in the Third Army Area (including 925 soldiers with Korean service, 2 799 without Korean service, and 714 civilians) was reported in this Journal by Radke and associates. The summary of the report stated in part that "Military personnel who had Korean service showed a slightly higher incidence of helminth infections but the total of the agents recovered was higher from military personnel who had no Korean service."

The relationship of bacteria of the paracolobactrum group to intestinal disease has been studied extensively at the 406th Medical General Laboratory and published in this *Journal* in 1954 and 1955.<sup>1,2</sup> Whether the presence of these organisms on vegetables is indicative of human fecal contamination is not sufficiently understood, nor is their pathogenicity completely known. Feeding enteric organisms of doubtful pathogenic nature to human volunteers is the only acceptable method for determining pathogenicity. To our knowledge, such experiments with adults have not as yet been performed. Therefore, there is insufficient specific evidence available at this time to indicate the danger of these organisms to young, healthy adults in the military service. On the other hand, several strains of paracolobactrum were recovered from a large number of service personnel involved in several food poisoning outbreaks,<sup>3</sup> and the role of certain members of this group of bacteria in diarrheas and dysenteries in children is well established. For this reason considerable caution is still required in recommending open purchase of salad vegetables in the Far East.

It is evident from this brief analysis of medical data that the military medical services faced a serious problem, and it is obvious that it was necessary for them to move cautiously. Similarly, any reluctance to change an existing, although costly, system is readily understood.

#### CURRENT AND CONTEMPLATED LABORATORY STUDIES

In addition to the field and laboratory studies referred to in previous sections, implementation of the tri-service directive necessitated other laboratory studies that were in more direct support of the program. These studies have been conducted by the 406th Medical General Laboratory and have been directed along three lines. It was first necessary to establish suitable standards of acceptability for vegetable produce and, after this was accomplished, to provide a continuing program of examinations on produce obtained from approved contract sources. Lastly, studies were to be undertaken to devise better laboratory techniques, and to investigate more thoroughly the actual role of night-soil fertilization in the transmission of enteric organisms.

Bacteriologic and parasitologic examinations of soils were required as a part of the preliminary inspection of farms. *Esch. coli* and ova of *Ascaris lumbricoides* were used as the principal indicators of fecal contamination. Although the presence of these organisms will indicate only approximately when contamination occurred, the examinations provided a good index to the infection potential in the soil. Since it could be assumed that both organisms would probably be found in a proportion of any soil samples,

it was improbable that any large number of ideally acceptable farms would be found. Therefore it was necessary to establish certain minimum standards of acceptability. This was accomplished by an extensive study on soils and vegetables obtained from an Army operated farm and farms of vendors then supplying produce under warranty and vegetables imported from the United States. These standards which have been defined in a previous section are considered to be realistic and practicable. They have been used as a basis for issuance of contracts as well as to control the acceptability of produce offered by contractors after approval.

As soon as purchases of salad vegetables were started under the provisions of the directive a program was instituted in the departments of medical zoology and bacteriology whereby representative samples of vegetables were examined for parasitologic and bacteriologic contamination. Procedures which have been standardized and adapted for routine use were employed for both types of examinations.

The extent of either type of contamination on vegetables has not been great. Parasitologic findings from routine examinations made during the latter half of 1955 are summarized in table 3, and bacteriologic findings for the same period are presented in table 4. In addition to *Esch. coli* paracolobactrum were also used as

\*\*Per cent of total number of specimens of a type

\* Principally salad vegetables few fruits and cooking vegetables represented

indicators of bacterial contamination. The vegetable most frequently contaminated with parasites was celery, 8.8 per cent of 125 samples contained ova of *A. lumbricoides* or *Trichuris trichiura*, while only 2.1 per cent of the lettuce samples were contaminated. Together these vegetables accounted for 5.8 per cent of the total number of parasitologically positive samples. Although the incidence of contamination with ova was high, the total number of ova found was relatively small. Only 15 ascaris and 9 trichuris eggs were actually involved.

*Esch. coli* was found in 2.7 per cent of vegetable specimens and *Paracolobactrum coliforme* in 7.3 per cent. Parsley was the principal offender, 11.4 per cent of the samples carried *Esch. coli* while *P. coliforme* was found in 15.7 per cent. The occurrence of the two bacteria on celery closely matched the relatively high rate of parasitologic contamination, rates for the bacteria being 7.3 per cent for *Esch. coli* and 11.0 per cent for *P. coliforme*.

Lettuce was infrequently contaminated with *Esch coli* (19 per cent) although the occurrence of *P coliforme* was fairly great (76 per cent)

Contamination on tomatoes, cucumbers, and green peppers was observed only infrequently. Because of this and the fact that they are easily washed, it is anticipated that these vegetables will be removed from the list of products that must be purchased from approved sources.

It should be noted that nearly all vegetables were received in "as delivered" condition; hence the extent of contamination was not necessarily indicative of what would be expected after the vegetables had been trimmed and prepared for serving. Interpretation of parasitologic examinations on vegetables was complicated by the fact that laboratory tests indicate that the examination procedure is only about 60 per cent reliable. Hence, it is possible that a comparatively high proportion of positive samples and ova might have been missed. However, the procedure is not selective for ova in particular stages of development.

Ova of ascaris and trichuris were found in 16.5 per cent of the routine soil samples examined during the last six months of 1955, while the rates for *Esch coli* and *P coliforme* were 6.5 and 2.7 per cent respectively. All samples were examined as a phase of the initial inspection of farms, and in some instances approval was not given because of evidence of excessive contamination.

It is recognized that these laboratory studies are essentially expedients and that information should be obtained on several additional points. A fundamental problem is to devise techniques or procedures whereby "recent" fecal contamination can be differentiated from contamination that might result from organisms already in the soil. This differentiation is important because the first type can be controlled but the latter cannot. For this reason, consideration is being given to the use of possibly shorter lived organisms such as enterococci as indicators. Also, the millipore filter technique as used by Stanetz and associates<sup>1</sup> for the recovery of micro-organisms may prove to be adaptable for soil and vegetable examinations, thus permitting the use of larger samples.

In view of observations such as those made in the United States by Rudolfs, Falk, and Ragotskie<sup>2</sup> and Wang and Dunlop<sup>3</sup>, it is evident that care must be taken not to impose excessively strict requirements on vegetable producers in areas such as Japan. These observations have suggested the desirability of comparing the occurrence of enteric bacteria and helminth ova in soils and vegetables in areas of Japan where different agricultural practices are followed. Such a study is in progress at the 406th Medical General Laboratory. The investigation has been expanded to per-

with a more comprehensive study of the role of vegetable produce in the epidemiology of dysentery and trichuriasis

### SUMMARY

Four of gastro intestinal infections among the United States Armed Forces and their dependents in the Far East has resulted in the past in elaborate precautions to avoid such diseases by empirical methods. By extending this concern to the matter of fresh vegetable procurement, the military prior to 1955 resorted to the costly expedient of obtaining its supply of these important foods from hydroponic farms and sources in the United States. Experience with a general food procurement program implemented in early 1955 has demonstrated that with well conceived and properly executed sanitary standards, it has been possible to develop in Japan and Okinawa a safe supply of salad vegetables on a scale sufficiently large to be practical and, equally important, to eliminate much unwarranted concern.

# DYNAMIC FACTORS IN PSYCHIATRIC DISCHARGES OF MIDSHIPMEN

DEAN J PLAZAK Lieutenant MC USN

THE GOAL of the United States Naval Academy is to provide midshipmen with a basic education and knowledge of the naval profession and by tradition and example to indoctrinate them with the highest ideals of duty honor and loyalty for the purpose of providing the naval service with capable junior officers

Adjustment to the program devised to carry out this goal necessarily requires that each midshipman accept the challenge not only of pursuing a college education but also of making an abrupt change from civilian to military life The entire summer before the freshman academic year is set aside to help the new midshipman with this transition Personal counseling with regard to problems which seemingly arise out of this adjustment is provided by each midshipman's company or battalion officers throughout the four years

When persistent problems appear to stem from long standing personality disorders or from psychiatric illness outpatient psychiatric evaluation and treatment facilities are available in the Academy's medical department and inpatient care is available at the U S Naval Hospital in Bethesda Md

Assistance in attaining and maintaining a healthy adjustment to the new environment is also provided through mental hygiene and leadership courses conducted by the department of psychology This program additionally provides confidence and support for midshipmen contemplating and later accepting needed outpatient psychiatric help

Each year approximately one tenth of the total midshipman population is disenrolled Fifty per cent of these midshipmen are discharged by reason of academic failure 10 per cent for serious or repeated violations of regulations and 10 per cent by reason of physical or psychiatric disability 30 per cent resign for personal reasons Difficulty in personal adjustment to the academy appears to be an important factor in all of the

disenrollments even if only the general reasons just listed are considered

In the course of detailed clinical evaluations conducted on these midshipmen referred for inpatient psychiatric care in 1955, it became apparent that the dynamic determinants of their illnesses appeared to be closely related to their specific difficulty in personal adjustment to the setting of the Naval Academy. The ability to establish a successful masculine relationship with both peers and authority figures seemed to be the most important criterion of successful adjustment. Knowledge of the reasons for inadequate adjustment was recognized as potentially valuable in reducing the number of yearly disenrollments.

Complete clinical records of 44 midshipmen discharged from the Naval Academy from mid 1948 to mid 1955, by reason of emotional disorders, were available for this study. In each instance, these records contained a complete physical, laboratory, and mental examination, detailed psychometric testing, including Wechsler Bellevue and Rorschach tests, comprehensive interviews with parents or guardians obtained by trained social workers, and verbatim interviews with the patients. The academic, health, personal, and disciplinary records of all of these patients were obtained for study from the registrar of the Naval Academy.

### PRECIPITATING STRESSES

Symptoms of illness in these midshipmen appeared at seven specific times of stress during the four years. Thirty-two of the 44 patients required inpatient care after their initial difficulty at one of these times, 12 after 2 or more of these 7 periods of stress (fig. 1).

Ten of the 44 midshipmen experienced difficulty during freshman class or "plebe" summer. They found the academy far different from what they had expected, were homesick, or felt unprepared for the emphasis placed on teamwork and competition. These reactions represented ambivalence with regard to dependency needs and lack of individual self-confidence and self-esteem. Three of these 10 midshipmen required inpatient psychiatric care at this time.

The return of the upperclassmen in the fall of the freshman year was described by 20 of the 44 midshipmen as the major source of their difficulty. They felt unable to meet such demands as were made on their behavior and performance by the upperclassmen. They were introduced at this time to such traditional practices as performing errands and chores and answering numerous questions by rote for demanding upperclassmen. This appeared to arouse precariously controlled aggressive feelings toward

The academic, health, personnel, and disciplinary records of all of these patients were obtained for study from the registrar of the Naval Academy.

### PRECIPITATING STRESSES

Symptoms of illness in these midshipmen appeared at seven specific times of stress during the four years. Thirty-two of the 44 patients required inpatient care after their initial difficulty at one of these times, 12 after 2 or more of these 7 periods of stress (fig. 1).

Ten of the 44 midshipmen experienced difficulty during freshman class or "plebe" summer. They found the academy far different from what they had expected, were homesick, or felt unprepared for the emphasis placed on teamwork and competition. These reactions represented ambivalence with regard to dependence needs and lack of individual self-confidence and self-esteem. Three of these 10 midshipmen required inpatient psychiatric care at this time.

The return of the upperclassmen in the fall of the freshman year was described by 20 of the 44 midshipmen as the major source of their difficulty. They felt unable to meet such demands as were made on their behavior and performance by the upperclassmen. They were introduced at this time to such traditional practices as performing errands and chores and answering numerous questions by rote for demanding upperclassmen. This appeared to arouse precariously controlled aggressive feelings toward

authority feelings of inadequacy under stress, and fear of attack. Sleepwalking was reactivated at this time in two patients who had experienced this difficulty in childhood. Ten of these 20 midshipmen required inpatient psychiatric care.

Figure 1 Specific stress periods leading to hospitalization.

A lack of desire to return from Christmas leave granted during the freshman year was expressed by 5 of the 44 patients. Their feelings appeared to be dynamically similar to those of the first two groups wherein a temporal opportunity was used to make their feelings more emphatic. Four of these men required inpatient psychiatric care at this time of stress.

The purpose of the two summer cruises taken prior to the sophomore and senior academic semesters is to train the midshipmen in the operational duties of watch and division officers and to assist them in adapting to the environment aboard ships at sea. Twelve of the 44 patients in this series appeared with various complaints in the psychiatric department at the academy prior to the sophomore class summer cruise. Eight required inpatient care. The remaining 4 of these 12 students appeared again before the senior class summer cruise and required inpatient care. They all appeared to be in panic over thoughts of the

relatively isolated confines of a ship and especially at the thought of leaving land. In addition, there were strong feelings of being unable to meet the responsibilities of an officer assigned a specific task which he must accomplish. The tasks that seemed to produce the most anxiety were those requiring individual judgment, such as directing a group of men in an assigned navigation problem. Irritability over having to sacrifice personal comfort, privacy, and desires because of the close relationships aboard ship was a problem to some of these 12 midshipmen.

The sixth stress period occurred at the time of the final physical and personal examination for commissioning, which takes place in the fall of the senior year, and the seventh in the two months prior to graduation. Fifteen of the 44 patients were admitted to the hospital at these times, most of them with physical complaints. Dynamically, these two groups displayed resistance to the assumption of the responsibilities of a commissioned naval officer. A substantial number used these opportunities to indicate their previously unexpressed personal desires for other life pursuits. Their attendance at the Naval Academy appeared to be an attempt to gain better relationships with paternal figures by accepting their fathers' goals as their own.

#### BEHAVIOR IN THE ACADEMY SETTING

Each of the 44 patients displayed an individualized response to the setting of the Naval Academy in terms of behavioristic difficulties. This was further reflected in the wide variety of diagnostic categories in which the patients were placed, varying from personality disorders to overt psychoses. However, their responses fitted into four major categories, with some types of behavior such as suicidal gestures and physical complaints common to all four. Lack of voluntary participation at the Academy in sports involving bodily contact was characteristic of all 44, and only 8 participated to any extent in team sports of non-contact type.

The four major categories of behavior responses to the Naval Academy setting have been designated as groups A, B, C, and D. The 12 patients in group A showed a behavior pattern characterized by passive resistance. They studied and met recitation standards, but did not pass examinations. Their disciplinary demerits were acquired by carelessness in personal appearance, tardiness in reporting for appointments, drill formations, and class formations, losing official papers and personal possessions, and having disorderly rooms. The performance of this group in intramural athletic competition was poor. Over half of the patients in group A complained frequently to the outpatient medical staff of headache, backache, and diffuse gastro intestinal upsets. Three of these 12 had over 5 hospital admissions for

complaints of this type before their psychiatric inpatient care began.

The 14 patients in group B displayed behavior which was aggressively resistant. Academically, they did not prepare assignments, did not meet recitation standards, and made little effort to pass examinations. They frequently gave "I don't know" as a recitation answer. These patients did not do well in their personal relationships with other midshipmen and were especially antagonistic to upperclassmen. Their demerits were acquired by failure to keep good military discipline, open disregard for rules, improper performance or neglect of assigned duties, and disorderly conduct in ranks of an attention getting nature. This group repeatedly attempted to submit resignations which were not accepted because parents or guardians would not consent. Such consent is necessary if the midshipman is under 21 years of age.

The six patients in group C openly questioned and challenged authority in the academic classes and in military and athletic activities. They were demanding of special attention and attempted to lure those in authority into long argumentative discussions. This group insisted that the regulations of the Naval Academy were at fault and were designed to irritate them personally and acquired their disciplinary demerits for unwarranted assumption of authority, unauthorized absence, and disrupting and disorderly conduct.

The 14 patients in group D made a concerted effort to appear to conform and behaved in a withdrawn, seclusive, ruminative fashion. They displayed little or no initiative, avoided responsibility, and assumption of authority, and would perform assignments in a slow but satisfactory manner only if it were mandatory. They were academically borderline, gradually falling into the "nonpass" category. Their disciplinary difficulties were caused by progressive deterioration of personal appearance and awkwardness in military and athletic groups.

A further means of objectively evaluating and categorizing dynamically significant behavior was provided by the aptitude for service\* system. This is a system designed to determine on a comparative basis within each class a midshipman's ranking in attitude, performance of duty, leadership, and military bearing. Rankings are made by fellow class members, upperclassmen, and staff members. The aggressively resistant patients in group B were consistently ranked low in military bearing, the "challengers" in group C low in service aptitude, the withdrawn patients in group D low in leadership. Most of the patients in all four groups ranked medium in all the other ratings. The difficulty in ranking patients from group A experienced by both

poors and authority figures, indicates the varying success of passive resistant behavior

### FATHER SON RELATIONSHIPS

Objective and subjective evaluations of the patients' relationships with their fathers were made in each of the 44 cases

Objective evaluation revealed that the father was deceased in 6 of the 44 cases, and in 4 instances had been replaced by a stepfather who was rejecting or withdrawn. In 4 of the 44 cases the parents were divorced, the child's custody awarded to the mother, and subsequent contact with the father either nonexistent or unfavorably looked on. In the remaining 34 intact homes, 16 of the fathers appeared to be dominant, rigid, unapproachable, difficult to please, and excessively demanding, 10 had a serious problem with excessive use of alcohol, 4 were unsettled in occupations or were drifters or unemployed, 3 were absent from the home most of the time by choice, and 1 was passive, unresponsive, and withdrawn.

Subjectively, 18 of the 44 patients complained of their fathers as difficult to get to know and to get along with, 14 were fearful of their fathers, 4 reported they had no father, 2 showed open dislike for their fathers, 2 knew other men they would have preferred as fathers, 2 described their fathers as chronically ill, and 2 expressed no opinion.

### MOTIVATION FOR ENROLLMENT AT THE NAVAL ACADEMY

In objectively determining individual motivation for coming to the academy, a notable lack of personal desire was found. It appeared that no midshipman in this study enrolled because of his own wishes but rather to meet one or more specific personality needs of others. Twenty six could not have been supported in college on a paying basis by their families, often because of poor financial planning. Twenty four enrollments were obviously used as a means of raising family prestige or social standing. Twenty two enrollments were desired by the father of the family, 10 ostensibly because the son "needed to learn discipline." In each of these 10 cases there was a history of a disciplinary problem at home, in school, or during a previous enrollment in a military school. This data again stresses the important role of identification with the father involved in the behavior of these patients, as well as the difficulty that many would experience in voluntarily resigning from the Naval Academy because of family and community repercussions.

### INTERRELATIONSHIPS AND DISCUSSION

The four groups of behavior responses to the Naval Academy setting, A, B, C, and D, and certain types of father son relation

ships were found to be significantly related. A father-son relationship was considered significant if it applied to 75 per cent of a behavior group. Patients in group A, characterized by passive resistant behavior, were fearful of or showed covert hostility to their fathers, and the fathers were dominant, rigid, unapproachable, demanding, and difficult to please. Dynamically, this group of patients had devised a passive means of expressing dissatisfaction that still allowed a never ceasing effort to try to obtain a much desired relationship, but bypassed the impossibility of a direct approach. Members of group B showed aggressively resistant behavior at the Academy, complained of fathers who were difficult to know and to relate with, or were openly hostile to their fathers, and the fathers were divorced, separated, absent frequently by choice, unemployed, or drifters. This group was much more openly expressive of the dissatisfaction felt toward an inadequate father and at the same time identified by behaving in the same "rule breaking" fashion.

Group C, who were openly questioning and demanding of authority, said they had no father or complained of a difficult relationship. Those fathers were deceased, some later replaced by stepfathers who were rejecting or withdrawn. These patients aggressively expressed their ambivalence over being forced to accept the paternal role in their families and over a continued need to be cared for as the son. Group D, the quiet withdrawn conforming patients, reported their fathers were sick or denied a difficult relationship. These fathers were objectively considered to have serious problems with excessive use of alcohol. This group displayed identifying behavior of a passive dependent quality and reflected the feelings of inadequacy and lack of self confidence of their fathers.

The patients in all four groups continued to relate to the setting of the Naval Academy as they previously did to their fathers. This was reflected in their specific disciplinary and academic difficulties. An insecure father-son relationship appears to predispose difficulty in adjusting to situations requiring further relationships with male peers and authority figures.

The appearance of suicidal gestures, physical complaints, and other examples of acting out behavior as initial symptoms of difficulty emphasizes the feeling that all these patients did not have a good enough relationship with any male authority to be based upon their experiences at home. The fear of failing in the eyes of their peers, families, and home communities was strong. The expression of physical or even serious emotional sickness as represented by a suicidal attempt seemed a more acceptable way out of an intolerable situation for these 44 patients than facing it directly.

The general lack of participation in group or body contact sports reflects the lack of desire for and inexperience in competition due to feelings of inadequacy and marked emotional investment in difficult family relationships.

Twenty seven of these patients were failing academically on admission to the hospital. All had intelligence levels of bright normal or above. This finding illustrates the well known interference with intellectual activity by emotional difficulties.

### CONCLUSIONS AND SUMMARY

Forty four clinical records of midshipman patients discharged from the United States Naval Academy for psychiatric reasons were studied to determine what significant dynamic factors led to their need for inpatient care.

Precipitating stresses in their illnesses were found to occur at seven specific times, dynamically related to feelings of dependency, repressed hostility, lack of good verbal communication with male parents, feelings of inadequacy with regard to responsibility and leadership tasks, and competition with peers.

Behavior patterns used in adjusting to the environment of the Naval Academy during the four years were found to fall into four general categories and to be closely interrelated with previous unsatisfactory father-son relationships. Dynamically, these techniques represented expressions of dissatisfaction with those relationships, and covert wishes to improve or change them.

Acting out rather than verbalization of feelings was characteristic of all of the patients. Presenting symptoms such as physical complaints were often related to an anticipated loss of respect by family, community, and peers in the event that they should request to resign from the Naval Academy.

Reasons for entrance into the Academy were usually found to be unrelated to the patient's personal desires, and met one or more specific personality needs of others, usually their fathers'.

Data of this type are recognized as potentially useful in screening Naval Academy applicants and in reducing the 10 per cent of the total midshipman population that is disenrolled each year for various reasons. The disciplinary and academic difficulties experienced by midshipmen discharged for psychiatric reasons are very similar to those experienced by midshipmen disenrolled for academic and disciplinary reasons.

Further exploration of the data evolved from these case studies appears to be indicated. Recognized factors not discussed in this article are previous community and peer relationships, attitudes and behavior of other midshipmen toward those having

difficulty in adjusting and resistance to early acceptance of need for psychiatric help. A long term statistical and dynamic study of all members of an entire class now in progress at the Naval Academy should provide valuable and needed control data for this case material not practical in the present study

---

### PHYSICIAN AND DISASTER

Plans must be made for proper reception and registration of casualties for skillful and rapid diagnosis of injuries for the utilization of recognized procedures and for the formation of teams of skilled auxiliary workers. To assure themselves of having an opportunity to render good medical service during a disaster and its aftermath physicians must take the lead in making certain that similarly careful planning has been done in the related fields of rescue communication transportation and fire and police work. Thus two distinct obligations face the physicians acquisition of recognized techniques for the handling of medical emergencies and stimulation of training of auxiliary workers. Men and women in related health fields are eager for the leadership which only the medical profession can give.

## Vivax Malaria Without Primary Attack in Korean Veterans

RICHARD S. HOMER *Captain, USAF (MC)*

THE conclusion that malaria never became a problem during the Korean campaign because of the routine use of chloroquine prophylaxis by the U S armed services has been supported by many investigators.<sup>1-4</sup> Malaria did become a problem, however, when the drug was discontinued and the troops returned to the United States.<sup>1-3</sup> The many and varied symptoms, plus a usual paucity of or often misleading physical findings, causes difficulty in making the diagnosis, as was well illustrated by Hall.<sup>5</sup>

Beginning December 1951, personnel of the U S armed services were given primaquine (15 mg base) daily for 14 days on the return trip from Korea.<sup>6</sup> This was done in an attempt to combat both the known tendency of Korean vivax malaria to recur after a latent period of 9 to 10 months and the known failure of suppressive chloroquine therapy to protect Korean veterans from relapse. This program has been effective but there have been cases of relapse reported despite the routine use of primaquine.<sup>7</sup>

The most important of the conclusions reached in previous studies were that (1) relapse of Korean vivax malaria may occur in the absence of an earlier primary attack, despite primaquine prophylaxis, and after the Korean veteran returns to the United States, and (2) it is difficult to establish the diagnosis, especially for medical officers not acquainted with the disease, because of the often misleading history and physical findings.

### CASE REPORT

A 21 year old Negro soldier was admitted to this hospital 2 August 1955 complaining of frontal headache, malaise, and sore throat of one day's duration. Onset was sudden and by the day of admission he was febrile but repeatedly denied having chills. Past history was significant in that he was stationed in Korea from February 1954 until January 1955 during which time he had no illnesses. He stated that he took the prescribed chloroquine in Korea and primaquine on the return trip to the United States.

---

From U S Air Force Hospital Beal Air Force Base Calif. Or Homer will be at Veterans Administration Hospital 5901 East Seventh Street Long Beach 4 Calif after 1 April 1957.

### Physical Examination

Physical examination revealed an acutely ill toxic man. His temperature was 101°F pulse 100 and blood pressure 122/75 mm Hg. Ear canals and drums were inflamed. The throat was markedly injected and the tonsils were enlarged and red but had no exudate. There was cervical axillary and epitrochlear lymphadenopathy. Heart and lungs were normal. Liver and spleen could not be palpated although there was moderate punch tenderness over the liver.

### Laboratory Studies

Complete blood cell count, urinalysis and a roentgenogram of the chest were within normal limits. A cardiolipin test was negative. No bile was found in the urine and urobilinogen was in normal concentration. Febrile agglutinins, heterophile antibodies, Weil-Felix agglutinations, van den Bergh reaction, cephalin-cholesterol flocculation test, stool examinations and roentgenograms of the gallbladder were within normal limits.

### Course in Hospital

For the first six days in the hospital the patient ran an intermittent spiking fever up to 105°F associated with extremely severe headaches. During this period he showed no response to large amounts of penicillin and chlortetracycline hydrochloride (aureomycin). Examination of the temperature curve on the fifth hospital day revealed that the temperature spikes came at 48-hour intervals with afebrile and asymptomatic periods between the spikes. During an afebrile period on the fifth hospital day trophozoites of *Plasmodium vivax* were found on a thin blood smear. More mature forms were found during a temperature spike the next day. The patient was then begun on the standard treatment of 1 gram of chloroquine immediately followed by 0.5 gram of chloroquine six hours later and then 0.5 gram per day for the next two days. Fifteen milligrams of primaquine base per day was begun with the chloroquine and maintained for 14 days. The patient showed no immediate response and became afebrile and asymptomatic. The liver tenderness persisted after he became afebrile but subsided by the end of the 14 days of therapy. He was discharged at the end of therapy and continued to be well on subsequent follow-up visits.

### DISCUSSION

Two other cases seen at this hospital and an additional case admitted to the 2473d USAF Dispensary were similar to this one in that there was no history of a previous attack of clinical malaria. This corresponds to findings of other studies.<sup>3,4,10</sup> In all four cases the "initial" attacks appeared in August or early September at least four months after the men left Korea. This corresponds to a latency period of 9 to 10 months inasmuch as the period of infectivity of Korean *vivax* malaria is between April and October.<sup>3,4</sup> It would seem that although the initial infestation

occurred in Korea, either the prophylactic chloroquine taken there prevented the appearance of clinical malaria,<sup>4</sup> or as is sometimes seen in untreated Korean vivax malaria, a primary attack never occurred.<sup>4,9,10</sup>

It is well known that chloroquine, even in therapeutic doses, will affect only the erythrocytic phase of malaria, and thus will not prevent relapses. Controlled studies of primaquine were reported to demonstrate that at doses of 15 mg of the base daily for 14 days, relapse of Korean vivax malaria would be prevented in 99 per cent of cases.<sup>7,8</sup> Use of this regimen for returning Korean veterans has decreased the rate of relapse, but the four cases described here support the observation of Hinson, Clove, and Pruitt<sup>7</sup> that occasional relapses do occur despite primaquine prophylaxis. In all fairness, it must be added that the only evidence that primaquine prophylaxis was taken in these four cases, is the statements of the patients themselves.

These cases illustrated both the difficulty of making a diagnosis of malaria when one does not suspect it, and the ease of diagnosis once the suspicion of malaria is aroused. Two cases were unusual in that chills were never experienced by the patients, nor seen by an observer. The most impressive features were the high fever and severe headache. Fever, stiff neck, and severe headache in one patient resembled encephalitis or meningitis, however, spinal fluid studies were within normal limits. All patients complained of malaise, anorexia, and in general presented a "flu like" picture. One patient complained of sore throat, two had nasal congestion, and three had pharyngeal lymphoid hyperplasia. Only one patient had a history of chills and fever every 48 hours, and fortunately the private physician who saw him initially had once practiced in an endemic malaria area of California and was familiar with the disease.

Splenomegaly was absent in all four cases, although it was present in 28 per cent of Hall's<sup>1</sup> series, and in the case recently reported by Rogers.<sup>5</sup> Hepatomegaly was not present but two patients did have punch tenderness over the liver. As in Hall's<sup>1</sup> series, many of the other physical findings were misleading, and often suggestive of diseases other than malaria.

None of the four patients had anemia, but one did have leukocytosis. In all patients, the cardiolipin test for syphilis was negative. As in Hall's<sup>1</sup> series the diagnosis of malaria was made with thin blood smears using Wright's stain. It is generally accepted, however, that the probability of making a correct diagnosis is increased when thick blood smears are used.

All four patients showed immediate response to the chloroquine-primaquine therapy as did the previously<sup>11</sup> cases. There was no evidence of primaquine toxicity in the Negro or Caucasian patients.<sup>11,12</sup>

In as many as 50 per cent of the cases reported by Hall, 14 diseases other than malaria were listed as the admitting diagnosis. Besides the causes for error in diagnosis discussed here and in Hall's article another important factor delaying diagnosis of malaria is a physician's lack of experience with the disease. These were the first cases of malaria seen by me and the other physicians who saw these patients initially. As was illustrated by these cases it is not safe to rule out the possibility of malaria because of previous prophylactic administration of chloroquine and primaquine.

### CONCLUSIONS

"A high index of suspicion for malaria is warranted in returning veterans with febrile illnesses in order to establish correct diagnoses." This "high index of suspicion" should be maintained despite the prophylactic use of chloroquine and primaquine. The warning should be heeded not only by military physicians but also by civilian physicians because many of the men returning from endemic malaria areas may have returned to civilian life before a relapse of malaria occurs.

# Tumors of the Testis in Infants

EVAN L. LEWIS *Lieutenant Colonel, MC USA*

MUCH has been written in the past 10 years on tumors of the testis, but from the literature one would think that the incidence of this disease in infants is rare. One of the most recent articles on the subject is that of Doyle,<sup>1</sup> who gathered 25 cases and added one of his own. In the past three years, three patients less than three years of age were admitted to this hospital with tumors of the testis. One of these tumors turned out to be a fibrosarcoma of the tunica albuginea, and the other two were undifferentiated adenocarcinoma (embryonal carcinoma). During this same period 17 adults were admitted with tumor of the testis. This suggests that the actual incidence in children is higher than we have previously believed.

Tumors of the testis may arise from any of the elements that comprise this organ. This includes tumors of connective and vascular tissue, as well as tumors of germ cell origin. Friedman and Moore<sup>2</sup> found 35 per cent of 922 tumors of the testis to be teratocarcinomas, 7 per cent were teratomas, 19 per cent embryonal carcinomas, 35 per cent seminomas, 1 per cent interstitial cell tumors, and 3 per cent rare or unclassifiable varieties.

As for tumors of germ cell origin, the generally accepted theory today is that they are all derived from a totipotent cell.<sup>3-5</sup> If this totipotent cell does not undergo differentiation, the seminoma is formed. Moore<sup>6</sup> and Friedman and Moore<sup>7</sup> preferred to call this tumor germinoma for that reason. With differentiation the tumor may go into one of two directions. It may form all three germ layers, in which case a teratoid tumor is formed, either immature (teratocarcinoma) or mature (teratoma). When this differentiation is not complete, an embryonal type of tumor is formed. This tumor is composed of primitive ectodermal tissue and may form a papillary adenocarcinoma, an undifferentiated adenocarcinoma, or an undifferentiated carcinoma with no attempt at glandular formation. The difference between this type of tumor of primitive ectoderm and the more vicious cytotrophoblast, which is principally trophoblast, is very small from the histologic standpoint in that the cells are similar and both arise from the same

---

From Tokyo Army Hospital Tokyo Japan. Col. Lewis is now assigned to Army Hospital San Francisco Calif.

ectodermal anlage. To the clinician, though, there is a considerable difference in survival rate, in rapidity of tumor growth and in mode and rate of metastasis.

Trophoblastoma is a differentiated cell similar to the Langhans cell of the chorion. It develops from primitive ectoderm. This cell metastasizes early and usually via the blood stream rather than by the lymphatics. If there are syncytial cells along with the trophoblastoma, then the tumor comes under the classification of syncytiotrophoblastoma, also termed chorioepithelioma.

Moore<sup>5</sup> suggested that the last three groups, namely, embryonal carcinoma, cytotrophoblastoma and syncytiotrophoblastoma, be lumped together. Yet there is enough difference in survival rates (65 per cent for embryonal, 16 per cent for the trophoblastomas) to make the differentiation.

The classification of an individual tumor is often not clear inasmuch as a given tumor may contain any one of the four major elements. A 7½ pound intra-abdominal tumor removed here was 75 per cent seminoma, but the other 25 per cent was made up of primitive ectodermal, trophoblastic, teratomatous and syncytial tissues.

It is now the practice to classify any given tumor according to the most malignant cell present according to the following scale, which begins with the least malignant and progresses to the most malignant: seminoma, primitive ectoderm, immature teratoid tissue, trophoblastoma and trophoblastoma with syncytium.

Table 1 shows the results obtained in the Walter Reed series (1942-1945)<sup>2, 4</sup> and with the above named classification gives some indication of prognosis and treatment.

TABLE 1

Type of tumor	5-year survival (per cent)	Average radiosensitivity (roentgen units)	Recommended tumor dose for maximum treatment (roentgen units)
Seminoma	85	800-1,500	2,000
Undifferentiated carcinoma	65	3,000-4,000	4,000
Teratocarcinoma	50	3,500-5,000	4,000
Trophoblastoma	16	4,000 plus	4,000

### CASE REPORTS

Case 1. A two-year-old white boy was transferred to this hospital 17 May 1954. Past history revealed that he had been operated on when seven days old for pyloric stenosis. Three months prior to admission

a plastic repair of the abdominal scar was done. Approximately two weeks prior to admission the parents noted an enlargement of the left testis. On 14 May 1954 the left testis was removed through an inguinal incision. On histologic examination the tumor was malignant type undetermined.

On admission to this hospital the inguinal sutures were in place without evidence of reaction. Physical examination revealed no other abnormalities. A roentgenogram of the chest was normal. Hemogram was normal and a urinalysis was negative. On 18 May 1954 a left radical retroperitoneal lymph node resection was carried out. There was no evidence of metastatic cells in the nodes. The final pathology report stated that the tumor was a fibrosarcoma of the tunica albuginea (fig. 1) which had replaced more than 60 per cent of the normal testicular tissue. No x-ray therapy was given and the patient was discharged two weeks postoperatively.

Figure 1 (case 1) *Fibrosarcoma of tunica albuginea*. Note typical fairly uniform pattern ( $\times 110$ )

On 22 October he was readmitted to this hospital because of the recent development of a pea sized lump in the left side of the scrotum. This lump was smooth in outline, firm, movable, and nontender. General physical examination and a roentgenogram of the chest were negative. On 26 October 1954 this scrotal mass was removed with considerable

surrounding tissue. The tumor was similar microscopically to the original tumor. Follow up at 18 months was negative.

**Case 2.** While having his two year old son treated in the outpatient dispensary for a laceration the father mentioned a swelling of the child's scrotum which had been present for from 2 to 3 months. The physician examined the child and advised immediate admission. The general physical examination revealed no abnormalities. The right testis was normal. The left testis was firm, irregular and measured 4 by 6 cm. It was not attached to the scrotal wall and the cord felt normal. A roentgenogram of the chest and an intravenous urogram were normal. A hemogram was normal and a urinalysis was negative.

The next day an orchiectomy was performed through an inguinal incision. Because the pathologist reported an undifferentiated adenocarcinoma (embryonal carcinoma) of the testicle (figs 2 and 3) a radical

Figure 2 (case 2) Undifferentiated adenocarcinoma (embryonal carcinoma). Cells of primitive ectoderm arranged in an undifferentiated pattern. Central area shows early attempt at pseudoglandula formation. (X 110)

retroperitoneal lymph node resection was carried out on the left side 2 August. All nodes were stripped to the diaphragm. Inasmuch as there was no evidence of metastases it was decided not to give this child postoperative irradiation. One year after surgery he was gaining weight normally, he appeared normal on physical examination and a roentgenogram of his chest revealed normal findings.

**Case 3** An 8 month-old white male infant was first seen 18 January 1956 because of a firm swelling of the left testis. The diagnosis of hydrocele was considered, and an attempt was made to aspirate the sac. This was unsuccessful and the parents were told by the local physician that operation was necessary. On 22 January the patient was admitted to an Army hospital. The physical examination on admission was negative except for a large 3 by 4 cm left testis which was firm and of regular consistency. The skin was erythematous at the site of the aspiration. The cord was not thickened and felt normal. A hemogram was normal and a urinalysis was negative. A roentgenogram of the chest revealed normal findings.

*Figure 3 (case 2) Undifferentiated adenocarcinoma. Another section showing more advanced glandular formation. This supports the diagnosis of undifferentiated adenocarcinoma ( $\times 110$ )*

On 24 January the left testis was removed through an inguinal incision. The pathologist considered the tumor an undifferentiated adenocarcinoma (embryonal carcinoma) (figs 4 and 5). There was no evidence of spread up the cord and the tunica albuginea was intact. The patient was transferred to this hospital and on 2 February a left radical retroperitoneal lymph node resection was done. All remaining tissue in the left the scrotum was completely removed because an attempt to aspirate this tumor. All the nodes were negative. The patient made an uneventful convalescence and on 14 February. Because the nodes were not invol

creasing opportunities for exposures to the aniline derivatives. Cross sensitizations among local anesthetics have been studied for many years and have recently been reviewed by a number of authors (Rothman, Orland, and Flesch<sup>3</sup>, Struss<sup>4</sup>, Baer and Meltzer<sup>5</sup>).

Within this relatively small group of related compounds several types of cross sensitizations that vary greatly in the width of the sensitization spectrum and are based on different mechanisms have been reported. The chemical groups on which the cross sensitizations were based are the following: (a) aniline (Goodman<sup>6</sup>), (b) an OH group in the para or meta position on the aminobenzene ring (Schwarzchild<sup>7</sup>), (c) a tertiary amine (James<sup>10</sup>), (d) benzoic acid with a tertiary amine in the side chain (Waldron<sup>11</sup>), (e) esters of para aminobenzoic acid with secondary or tertiary amines in the side chains (Rothman, Orland, and Flesch), and (f) alkyl esters of para aminobenzoic acid (Laden and Rubin<sup>12</sup>).

Studies by Phillips<sup>13</sup> on cross sensitizations among certain local anesthetics and sulfonamide drugs revealed that, among subjects suffering from dermatitis due to various sulfonamide drugs, 68 per cent reacted to cutaneous tests with sulfanilamide, 30 per cent reacted to sulfapyridine, 21 per cent to sulfathiazole, 11 per cent to sulfaguanidine, and 7 per cent to sulfadiazine, while 16 per cent reacted to procaine hydrochloride. This shows that in a group of subjects hypersensitive to sulfonamide drugs the incidence of hypersensitivity to procaine hydrochloride is greater than to sulfaguanidine and sulfadiazine. Sulzberger and associates<sup>14</sup> observed cross sensitization to para aminobenzoic acid in two of eight subjects with dermatitis due to sulfonamide drugs, and one of these subjects also reacted to procaine hydrochloride.

The cross sensitization among paraphenylenediamine and azo-dyes are of practical importance because of the not infrequent occurrence of dermatitis due to azo-dyes in nylon stockings, with cross sensitization to paraphenylenediamine as described by Dobkevitch and Baer<sup>15</sup>. This reaction is based on the fact that both substances undergo transformations in the skin which lead to the formation of the same intermediate products. Baer, Leider, and Mayer<sup>16</sup> were able to show that this type of cross sensitization probably also extends to some of the azo-dyes which in the United States are certified for use in foods, drugs, and cosmetics. The cross sensitization among certified azo-dyes, aminobenzoic acid, quinones, and paraphenylenediamine is of decided importance clinically but has not been adequately investigated, although an investigation is being pursued by the same workers.

The term "cross sensitization" as employed here refers to the phenomenon in which a given sensitization crosses over among

# Cross Sensitization in Eczematous Contact Dermatitis

WILLIAM J. WAGNER *Lieutenant, MC USNR*

**T**HE PROPENSITIES for cross sensitization in allergic eczematous contact dermatitis have been considered by many investigators. Among the original studies of allergic sensitizations were those by Jadassohn<sup>1</sup> on reactions due to topically applied medicaments. Routine and systematic search for allergenic topical medicaments as causal or contributory factors in allergic contact dermatitis and other eruptions was first suggested by Goodman and Sulzberger.<sup>2</sup> These investigators proposed that patients who on the basis of clinical evidence were suspected of having developed allergic hypersensitivity to one or more topical medicaments be subjected to patch tests with a therapeutic tray and a standard series of commonly used topical medicaments. This procedure helps to ascertain with a considerable degree of accuracy any existing allergic sensitizations to these topical agents. The systematic elimination of those topical medicaments that are almost certain to cause aggravation and often also spreading of an existing dermatosis has proved itself to be of the greatest practical importance. One must, however, be aware of the fact that these tests cannot prevent or forecast subsequent development of allergic sensitizations to other topical medicaments.

Bloch's<sup>3</sup> classical study in 1911 on the nature of iodoform hypersensitivity showed that certain cases of multiple sensitizations which might have been classified as polyvalents although specific actually represented cross sensitizations among a number of chemically and hence immunologically related compounds. Moreover his study explained the previously puzzling fact that some patients experienced specific allergic sensitizations to agents which they had never previously encountered.

Cross sensitization has been investigated frequently since Bloch's work as discussed by Sulzberger. Studies on cross sensitizations among a group of compounds containing aromatic amines as part of their molecule are by no means new, but are of renewed interest at the present time because of the ever in-

sediment revealed numerous red blood cells and 6 to 8 pus cells per high power field

On 12 January most of his flank pain had subsided and an intravenous pyelogram was normal with no evidence of a calculus. It was presumed the calculus had passed.

After surgical consultation the patient was transferred to the surgical service for repair of the inguinal hernios. On 10 February a left inguinal hernioplasty was performed under spinal anesthesia, using Pontocaine (brand of tetracaine hydrochloride). On 12 February the patient was noted to have an acute vesicular eruption of the lower half of his back extending onto the buttocks, which was thought by the surgeon and author to be due to Merthiolate (brand of thimerosal) applied in preparation for the spinal anesthesia, but subsequent investigation revealed that tincture of benzalkonium chloride had been used for skin preparation. The rest of the patient's body was involved in an urticaria-like eruption. He was receiving penicillin at the time. The eruption rapidly subsided and on 5 March a right inguinal hernioplasty was performed. Merthiolate was not applied to any portion of his body for preoperative skin preparation. The surgeon used only phisohex and water to prepare the abdomen and the anesthetist used tincture of benzalkonium chloride prior to the spinal anesthesia. Pontocaine was again used as the spinal anesthetic. About 12 hours after the completion of the operation the patient was again noted to have an acute, vesicular, and severely pruritic eruption that rapidly became generalized to most of the body surface but remained most severe in the area of the application of the tincture of benzalkonium chloride. The eruption subsided in four or five days with the application of continuous wet dressings and a bland drying cream.

After the acute reaction subsided the patient was open patch tested to three samples of tincture of benzalkonium chloride obtained from stock solutions in each of the main operating rooms and to undiluted Merthiolate. Twenty-four hours following the patch tests there was noted an acute vesicular eruption at the site of the benzalkonium chloride applications while at the site of the Merthiolate application there was no reaction whatsoever. Subsequently he was patch tested in a new site to an aqueous solution of benzalkonium chloride and adhesive tape. After 48 hours no reaction was noted to either of these patch tests.

The dye used in the benzalkonium chloride (tincture) is D&C red No 39 commonly called alba red (ortho [para (beta beta prime dihydroxy diethylamio)-phenylazo] benzoic acid). The benzalkonium chloride solution used at this hospital is a 0.1 per cent solution containing alcohol, acetone, distilled water, and 0.02 per cent alba red dye.

On 21 March patch tests to Benadryl (brand of diphenhydramine hydrochloride), sulfadiazine, Benzocaine (brand of ethylaminobenzoate), Pontocaine, Pyribenzamine (brand of tripeleminamine hydrochloride)

several chemically related compounds. These cross sensitizations can be explained by the following possibilities of an immunochemical relationship between the primary and the secondary allergens<sup>17</sup>

1 The primary allergen and the secondary allergen may be so closely related immunochemically (*e g*, contain identical allergenic groups) that the sensitized cells cannot differentiate between them and thus react toward them as if they were identical (group specificity)

2 The primary allergen is converted (reduced, oxidized et cetera) in the body into an agent which is identical with or so closely related to the secondary allergen that the sensitized cells cannot differentiate between them

3 The secondary allergen is converted in the body into an agent which is identical with or so closely related to the primary that the sensitized cells do not differentiate between them

4 Both the primary and the secondary allergens are converted in the body into agents which are either identical or so closely related that the sensitized cells do not differentiate between them

These possibilities of direct cross sensitizations must be differentiated from indirect cross sensitizations or reactions which are produced by concomitant factors. Thus certain cross reactions<sup>18</sup> may occur when a sensitizing compound contains in addition to its principal allergen one or more other substances with allergenic potential (*e g*, contaminants) which themselves may give rise to independent sensitizations or elicit dermatitis in already sensitized skin

### CASE REPORT

A 39 year old man was admitted to this hospital on 7 January 1956 because of tight flank pain and hematuria of 30 hours duration. Past history failed to reveal evidence of previous episodes of abdominal pain, hematemesis or tarry stools. He had been in the naval service from December 1941. His mother and a sister died of tuberculosis. There was no family history of cancer, diabetes, calculi or previous skin diseases except that he was told he had exhibited sensitivity to a sulfa drug\* in 1949. The specific sulfa drug was unknown.

Physical examination on admission showed only tight flank tenderness producing pain radiating into the right anterior abdominal wall and into the right testicle. Temperature was 98.6°F, pulse 68 and blood pressure 120/62 mm Hg. Inguinal hernias were present bilaterally. A roentgenogram of the chest was normal. The white blood cell count, differential, red blood cell count, hemoglobin and sedimentation rate were reported as being within normal limits. Examination of the urine

# Ruptured Omphalocele

ROBERT C RAY, *Captain, MC USN*

**A**N OMPHALOCELE is caused by persistence of the normal fetal condition in which the mid gut is transferred temporarily into the base of the umbilical cord. The protrusion, which occurs in the fifth to twelfth week, probably results from an inequality of growth between the abdominal parietes and the more rapidly developing abdominal organs. During this period the rate of growth of the abdominal cavity accelerates, and usually by the tenth or eleventh week it is of sufficient size to reaccommodate the displaced viscera.<sup>1</sup>

Sometimes the inequality in size between abdominal cavity and abdominal viscera persists, and the intestines and a portion of the liver remain in the base of the umbilical cord. Other organs that occasionally are protruded include stomach, spleen, pancreas, and transverse and descending colon. Eventration of liver and intestines occurs in about 1 in 10,000, and herniation of intestines alone in 1 in 5,000 births.<sup>2</sup>

When a child is born with this condition, the displaced abdominal contents are covered only by a translucent sac through which the organs can plainly be viewed.<sup>3</sup> Occasionally the sac is ruptured in utero or during parturition.

Infants with omphalocele must undergo prompt and radical repair if any hope is to be held for their survival. Optimum conditions are presented if the sac is intact and small, and the peritoneal cavity sufficiently developed to permit a one stage procedure without overcrowding. Trying to put "two pounds in a one pound bag" will result, as observed by Denman and Lomas,<sup>4</sup> only in respiratory embarrassment, compromise of venous return, or possibly a mechanical obstruction of the intestinal tract. When a large sac must be returned to a small, underdeveloped peritoneal cavity, a two stage procedure is necessary to create, by undermining, skin flaps which are large enough to cover the protruded organs. Even with this lifesaving measure, the skin must sometimes be closed under such tension that some embarrassment of vital function occurs.

---

From Station Hospital U S Naval Station Kodiak Alaska. Capt. Ray is now assigned to U S Naval Hospital San Diego Calif.

When the sac is ruptured at birth the hazard of infection is superimposed upon an already precarious situation and prior to the advent of chemotherapy none of these infants survived the peritonitis which ensued. When rupture occurs during delivery the outlook is more favorable than when it occurs in utero. Rupture during parturition as in the case reported by Lane<sup>3</sup> still presents the sac content in a somewhat pristine state whereas a gut that has been constantly bathed in amniotic fluid becomes thickened and edematous. Such a case was described by Bell and Brown.<sup>4</sup> This further increases its natural volume and makes the problem of replacement or cover more difficult.

### CASE REPORT

On 4 July 1956 a 17 year-old primagravida was delivered of a full term female infant weighing 5 pounds 10 ounces. The prenatal course had been uneventful and uncomplicated. The patient was delivered by low forceps after a 6-hour labor.

At birth it was noted that the infant had a large ruptured omphalocele. The coils of gut were swollen and had a darkly reddened somewhat granular appearance. They were matted together and it appeared that rupture had taken place in utero and some time previously.

The infant was cyanotic and had a weak feeble cry. No other gross abnormalities were evident. The everted organs were covered with a warm moist sterile dressing and a small dose of caffeine and sodium benzoate was administered. The stomach was intubated with a No. 12 French catheter and the infant was placed in an incubator in an oxygen-enriched atmosphere.

Three hours after birth under light open-drop ether anesthesia the dressings were removed and the coils of gut gently lavaged with physiologic saline solution. It was found that a portion of stomach the duodenum the mid gut and the major portion of the hind gut were everted through a musculofascial defect about 8 cm. in diameter. Only a small remnant of sac was in evidence. This was attached about the umbilical vessels which lay in the left mid portion of the defect. The loops of the gut were grossly thickened and edematous. There was no evidence of volvulus or of atretic stenotic or duplicated portions of the intestinal tract.

Only a small portion of the viscera could be replaced in the peritoneal cavity. Accordingly flaps were fashioned by extensive undermining and the skin was closed under a moderate amount of tension.

The infant reacted well and was returned to her incubator in good condition where she was continued on gastric suction and started on an intensive course of penicillin and dihydrostreptomycin sulfate.

Continuous gastric suction was maintained for 12 hours at the end of which time the tube was removed because of temporary respiratory em-

barrassment Thereafter, the infant was intubated and the gastric content aspirated every four hours

Fluids consisting of equal parts of 5 per cent dextrose in distilled water and of normal saline solution were administered parenterally in the amounts of 20 ml per pound of body weight per 24 hour period This kept the infant a little on the "dry side " but true dehydration was never a problem under this regimen

Beginning on the second day small amounts (60 ml) of 5 per cent dextrose were given by gavage following gastric aspiration and shortly thereafter this was replaced by half strength house formula

On the fourth day high pitched peristaltic sounds were audible Oral feedings in small amounts (from 30 to 45 ml) were started and were avidly taken by the infant A portion of the feeding would sometimes be propulsively vomited a few minutes after ingestion Following emesis the infant would be refeed and would nurse eagerly The possibility of a high mechanical obstruction was considered but the general condition of the infant remained fairly good and it was believed that all these manifestations could be explained by the slow recovery of tone of the thickened edematous bowel Although the vomiting persisted to some extent until the tenth day some of the feeding was being retained

Small twice daily, normal saline enemas were started on the fourth day with recovery of much meconium and thick, ropy mucoid material On the tenth day the infant began to pass meconium spontaneously and two days later the first stool containing digested milk curds appeared Following this progress was rapid and the infant was discharged home in the fourth week Weight at time of discharge was 7 pounds and 4 ounces

Figure 1 taken on the day of discharge shows the large ventral herniation and the crusted but firmly healed operative wound Unfortunately preoperative photographs were technically unsatisfactory

Figure 1 Photograph taken in the fourth week. Note the large ventral herniation and the crusted but firmly healed operative wound.

The child has been seen periodically as an outpatient. She continues to thrive and gain weight. No other congenital defects have been discovered to date. It is estimated that at her present rate of development she will be ready for the second stage operation in from 12 to 15 months.

#### BACK TO THE BOTTLE

No compelling evidence of physiological advantage or disadvantage attending the early feeding of solid foods has appeared. One thing seems to have been shown—the infant's digestion and assimilation are much more adaptable than was once thought, but it is an open question whether we should take advantage of this fact. In an age in which civilization is constantly chipping away at the simple uncomplicated animal aspects of human life, there seems reason to protest against any hurry to relinquish the natural suction of one warm liquid food in favor of the cultivation of a battery of acquired tastes by the unnatural means of spoon and cup.

p 779 June 23 1956

## A MESSAGE FROM THE A M A

Since July 1952, the Council on National Defense of the American Medical Association has conducted an opinion survey among physicians being released from active military service. The questionnaire used in the survey is primarily designed to obtain pertinent data based on the physician's observations and opinions while in the Armed Forces, concerning the utilization of physicians and the medical staffing conditions in the uniformed services. The questionnaire also calls for comments and suggestions of ways to further improve the medical services as well as ways and means whereby organized medicine can be of greater assistance to military physicians.

The following report is based on the returns received in 1955. During that 12 month period, the Council sent out 3,651 questionnaires, of which 2,191 were completed and returned. This represented a 60 per cent response.

**Date of Graduation from Medical School.** About half of the physicians replying (1,108) were graduated from medical school between the years 1945-1949, the second largest group, 503 or 23 per cent, graduated in 1950 or later. There were 449 or 20 per cent graduating between the years 1940-1944. Less than 2 per cent graduated before 1940. Eighty-nine failed to indicate the year of graduation from medical school.

**Years of Internship and Residency.** As was the case in the summary report covering the last six months of 1954,<sup>1</sup> the largest group replying to this question (497 or 23 per cent) had completed three years of residency training, while the second largest group (450 or 20 per cent) had had no residency training at the time of entrance on active military duty. There were 369 or 17 per cent with one year of residency training, 347 or 16 per cent with two years, and 268 or 12 per cent with four years. Those who failed to answer the question totaled 260.

**Occupation at Time of Entering Service.** The largest groups of physicians who served in the Army (28 per cent) and the Air Force (32 per cent) were engaged in general practice at time of

---

<sup>1</sup>From the Council on National Defense of the American Medical Association. The views and opinions expressed are not necessarily those of the Department of Defense.—Editor

entrance on active duty while the largest group in the Navy (26 per cent) were in residency training. The last summary report reflected the largest groups in all three services were engaged in residency training prior to active military service. In the Army group specialty or industrial practice was second while in the Navy it was general practice and in the Air Force it was residency training. There were 12 per cent of the Navy group, 10 per cent of the Air Force and 5 per cent of the Army engaged in internship training immediately prior to entrance on active duty.

**Number of Physicians Holding Board Certificates.** Of the 290 persons responding to this question, 128 holding specialty board certificates were in the Army, 93 were in the Navy and 69 were in the Air Force. The specialties covered over 19 different fields of which the largest was internal medicine, the second largest was pediatrics and the third largest was surgery. It is interesting to note that in the previous summary report<sup>1</sup> surgery was first, followed by pediatrics and internal medicine. By branch of service, a total of 25 per cent of those responding in the Army and Navy and 17 per cent of those in the Air Force had specialty board certificates.

**Reserve Status.** Of the 2,191 physicians reporting, 764 indicated that they retained their reserve commissions while 1,407 resigned. Twenty did not respond. In the Army, 242 retained their commissions and 722 resigned. The Navy had 351 retaining and 182 resigning and the Air Force had 171 retaining and 503 resigning.

**Distribution by Rank at Time of Discharge.** The majority of physicians in the Army and Air Force held the rank of Captain at the time of their release from active military duty. In the Navy, the majority were in the rank of Lieutenant (junior grade). Over 97 per cent of the reporting physicians, or 2,135, answered this question. The survey indicated that approximately 27 per cent of those who reported were in the lowest rank while 64 per cent held the rank of Captain or Lieutenant (Navy). There were about 7 per cent with the rank of Major or Lieutenant Commander and higher.

**Government Medical Education Received.** Of the 2,191 physicians responding, 1,153 stated that they had received assistance from the Government in their medical education. There were 1,013 who indicated no governmental assistance and 25 failed to answer the question. The largest single group receiving governmental assistance was under the Navy V-12 Program. The next largest groups were under the Army Specialized Training Program and the GI Program.

**Training Received While in Service** There were 1,814 physicians who answered this question concerning the types of military medical training received while on active duty, while 377 physicians did not respond to the question. All of those responding indicated that they had received additional training or experience in service schools, 916 in the Army, 317 in the Navy, and 581 in the Air Force. The Medical Field Service School accounted for the largest number, with the School of Aviation Medicine accounting for the second largest group. In the Army group, 87 per cent received the Basic Course training of the Medical Field Service School, while 13 per cent in the Navy and 41 per cent in the Air Force attended the School of Aviation Medicine.

The second part of the results of this interest opinion survey will be reported in the next issue of this *Journal*.

#### Rx NOSE DRDPS

Do not prescribe nose drops unless they are truly indicated. If they are indicated be sure to use a preparation that does not disrupt the physiology of the nasal mucosa and impair its native ability to combat infection. Oils, aromatic irritants, and antiseptics are unphysiologic. Nose drops should be aqueous, isotonic, and slightly acid. Any doctor can write an extemporaneous prescription for nose drops that fulfills these requirements, and such a medication is superior to any of the proprietary preparations for most patients.

## NAVY SURGEON GENERAL RECEIVES FRENCH MEDAL OF HONOR

Rear Admiral Bartholomew W Hogan Surgeon General of the U S Navy was decorated on 10 January 1957 with the "Medaille de vermeil" the Medal of Honor of the French Naval Medical Service

Rear Admiral Louis Mornu Naval Attache at the French Embassy in Washington D C presented the medal in recognition for the distinguished services Admiral Hogan rendered to the French Navy Medical Corps

In accepting the decoration Admiral Hogan stated that to receive this honor from such a great nation was truly a rare privilege and a proud moment not only for him but for the Medical Department of the U S Navy Official acceptance of the medal will require Congressional approval

**PREVENTIVE MEDICINE COURSE FOR MEDICAL OFFICERS**

The Military Preventive Medicine Course (Course 8037) that will begin on 3 September 1957 at Walter Reed Army Institute of Research, Walter Reed Army Medical Center, Washington, D. C., presents interesting opportunity for medical officers of the Armed Forces.

The course concerns the prevention and control of disease and injury in the military as well as in civilian communities. Emphasis is placed on the global aspects of military preventive medicine with particular attention to health problems of the arctic and tropical areas. Covering 48 weeks of academic studies, the course includes field trips or investigations and individual or committee studies. Selected Army graduates of the course will be eligible for entry into the Army's recently announced preventive medicine residency program.

The American Board of Preventive Medicine has approved this course as an equivalent of its requirement for the Master of Public Health degree. A bill is now before Congress which would authorize the granting of postgraduate degrees including that of Master of Public Health by the Walter Reed Army Institute of Research.

Regular Army Medical Corps officers or qualified physicians who accept commissions in the Regular Army are eligible for the course. Qualified officers from the Navy and Air Force medical services, the U. S. Public Health Service, and representatives of other governmental agencies may be admitted by mutual agreement between the Army Surgeon General and the chief of the government agency desiring to participate. Civilian physicians may apply by writing to The Surgeon General, Department of the Army, Washington 25, D. C. Attention: Personnel Division. Military personnel should apply through appropriate channels.

## Reviews of Recent Books

OFFICIAL HISTORY OF THE CANADIAN MEDICAL SERVICES 1939 - 1945  
 Volume One Organization and Campaigns Edited by W R Feasby M D  
 568 pages illustrated in color with paintings and photographs by Canadian War Artists and Photographers Maps drawn by Captain C C J Bond Published by Edmond Cloutier C M G A O D S P Queen's Printer and Controller of Stationery Ottawa, Ontario Canada 1956  
 Obtainable from the Superintendent of Government Publications Department of Public Printing and Stationery, Ottawa, Ontario, Canada Price \$5 postpaid

The medical administrative histories published through the past decade have had varying degrees of merit but the present volume would seem to surpass them all Except for one or two weaknesses, it is a brilliant example of how to write military medical history

The treatment of the subject matter appears to be objective and fairly presented The historian treats equally the strengths and the weaknesses of the medical services and their effect upon the war effort Particularly significant from the organizational and administrative viewpoint are the opening chapters and the later chapters beginning with Chapter 19 through the remainder of the volume

Under the able editorship of Dr W R Feasby, Canadian Medical Historian and his associates, this volume—one of two—treats the Canadian Medical Services in World War II The Royal Canadian Army, the Royal Canadian Navy, the Royal Canadian Air Force and the Royal Canadian Dental Corps along with the contributions of the civilian services connected with the medical aspects of the war effort are described in terms of medical organization and development to support the military mission in the many campaigns of World War II Large scale topics treated include those of manpower procurement and assignment of medical personnel The narrative carries through until the reader is aware of how these large scale problems had tangible meaning in terms of winning or losing a battle

Thus never are functional problems isolated from the military framework of command and operations insofar as the Mediterranean and European Theaters of Operations are concerned Beginning with background chapters about the military medical service on the eve of war and the status of mobilization plans the volume traces the overseas movement of troops and follows them campaign by campaign through the Dieppe Raid the Sicilian Campaign the Invasion of Normandy, the Rhineland Offensive and the Final Phase and Occupation Accompanying this extensive narrative treatment are beautifully executed maps and illustrations in color which this reviewer has not seen in any other medical history of the period

The one weakness is Chapter 18 "Hong Kong" a three page summary chapter which represents the only treatment of Pacific warfare. Equally disappointing is the fact that there is no mention of the China Burma India Theater except briefly on page 570.

Perhaps the serious student comparing the medical services of the Allies would also like to know in more detail the types of documents on which the historian has based his narrative.

This volume together with the previously published volume on clinical medicine completes the official historical record of the Canadian Medical Services. It is a record that all serious students of medical history—whatever nationality and whatever service—can study with rich reward. It is a volume that reads equally well to the student of military history. —*MAE M. LINK, Ph D*

**BOTANY** by *Paul Weatherwax*, 3d edition 509 pages illustrated W B Saunders Co Philadelphia Pa. 1956 Price \$5.75

This book was first printed in 1942 as a text for a basic collegiate course in general botany. In the present edition errors have been corrected and difficult sections clarified.

The work is divided into two parts the first dealing with general plant morphology and physiology. Structure nutrition growth photosynthesis reproduction ecology and plant communities and economic botany are well covered. Particularly good are chapters on dormancy and seed dispersal heredity and evolution. The second part describes the various classes of plants including the cryptogams with short notes on botanical history and plant fossils.

The numerous illustrations are clear and are so placed in relation to the text that reference to them is easy a desirable feature sometimes not found in scientific books. There is a glossary of over 1200 definitions and a useful index. The book is an excellent text for pre medical and pharmacy courses. —*LOUIS H. RODDIS Capt MC USA (R L)*

**THE HABIT OF TOBACCO SMOKING** by *W Koskousk* M D 292 pages Staples Press Limited London England Publishers Distributed in U S A by John de Graff Inc New York N Y 1955 Price \$5

This book is divided into two parts. Part 1 (historical review) describes the discovery of tobacco the forms of tobacco used and the various customs and practices associated with the tobacco habit that have evolved through the years to the present time. The great significance that the use of tobacco has had on the economic psychological biologic and social development of society is described. The statistics presented emphasize clearly the staggering economic importance of tobacco.

Part 2 (the action of tobacco and its compounds on the human organism) reviews present day knowledge of the action of tobacco broken down into the various active principles and their action on the

systems of the body. The data given are factual and the author presents these for review without crusading for or against the use of tobacco. He has been very objective in his presentation and to those physicians who wish a very clear and concise summary of the influence of tobacco under various conditions this book is recommended. For those physicians who have followed only radio television and news print comments on the relationship between tobacco and malignant disease this book presents a digest of the evidence available, and should serve to crystallize their thoughts on the subject. This book will give the busy physician factual ammunition to better answer the many questions asked by patients. Dr. Koskowski also points out the many channels of experimentation which are still open to investigators and emphasizes the tremendous problems yet to be answered.

The style of the book is light and pleasant, and the statistics are well placed. This book should appeal to physicians in all major specialties of medicine. —PAUL C. LE GOLVAN, Lt Col MC USA

BIOCHEMISTRY FOR MEDICAL STUDENTS by William Veale Thorpe M A (Cantab) Ph D (Lond) 6th edition 542 pages 48 illustrations J B Lippincott Co Philadelphia Pa 1956 Price \$6.75

Initial brief chapters of this book on the physicochemical principles pertinent to biochemistry are followed by a presentation of the fundamental chemistry of the major categories of foods animal pigments enzymes and of oxidation and reduction. Subsequent chapters are devoted to the composition of blood tissues and excretory products the biochemistry of absorption and digestion and the intermediary metabolism of carbohydrates, lipids and proteins. This partial inventory will serve to identify the classical pattern of a biochemistry text intended for the medical student. Like its predecessor the current edition has the virtue of clarity of language and of readability applied to an extremely large amount of diverse subject matter.

The volume contains a brief but apt chapter on the use of isotopes in biochemical studies. Similar attention is accorded the metabolic interrelationships and syntheses occurring in vivo. Separately and together these chapters should facilitate the student's transition from the relative security of his textbook to the less familiar terrain of the current literature in biochemistry and physiology. Equally welcome is the chapter dealing with "detoxication" processes which the title entitles and develops as the metabolism of foreign organic compounds.

The treatment of nutrition and of related topics is laudably conservative although the references to feeding patterns and to certain foodstuffs in Great Britain might be expected to have a certain relevance for the American reader. The chapter on hematology is identical with that which appeared in the previous edition. Reasonably sufficient as an introduction to the subject.

chemistry this chapter nevertheless fails to convey the significance of hormonal interrelationships in the intact organism

The author has made excellent use of diagrammatic representations to summarize cardinal metabolic pathways e g the tricarboxylic acid cycle and interrelationships in the metabolism of proteins fats and carbohydrates In the presentation of tables and figures the book is exemplary The layout of the many formulas used is particularly effective and constitutes an invitation to learning

—THADDEUS J DOMANSKI Col USAF (MSC)

THE YEAR BOOK OF MEDICINE (1956-1957 Year Book Series). Part I Infections by Paul B Heeson M D Part II The Chest by Carl Muscheheim M D Part III The Blood and Blood Forming Organs by William B Castle M D Part IV The Heart and Blood Vessels and the Kidney by Tinsley R Harrison M D Part V The Digestive System by Franz J Ingelfinger M D Part VI Metabolism by Philip A Bondy M D 744 pages illustrated The Year Book Publishers Inc Chicago Ill 1956 Price \$6 75

In this era of increasing abundance of medical literature and the tendency to condensation the Year Books have been timely and valuable This volume continues in the successful pattern of its predecessors by providing excellent abstracts of the world literature prepared by recognized authorities on infections the chest the blood and blood forming organs the heart and blood vessels the kidney the digestive system and metabolism Included as always are many sagacious and often pungent annotations by the editors a comprehensive index so often lacking in medical books and numerous illustrations the latter of a much higher quality than heretofore seen in this series

Although in no way a substitute for medical literature as such by reason of necessary brevity these groups of abstracts permit the reader to keep up to date in broad subspecialty fields that may lie outside his current experience The helpfulness of the Year Books of Medicine to the physician preparing for specialty board examinations is becoming legendary

The general practitioner as well as the internist will profit by having this volume close at hand It is a real bargain

—ROBERT K MOXON Comd MC USN

SURGERY OF THE HAND by Sterling Bunnell M D 3d edition 1 079 pages 1 047 illustrations and 9 color plates J B Lippincott Co Philadelphia Pa 1956 Price \$22 50

This text is again revised in a thorough manner and brought up to date with the recent advances in this specialized field of surgery The revision enlarges the book by some 130 pages and includes additional text and illustrative material In addition there are revisions in the older material as well which makes for better readability

This book is unique in medical literature It is the only complete text on surgery of the hand in publication indeed little more can be

learned through outside reading. The material is well organized and carefully presented, and is based upon the vast personal experience of the author and his associates. It is highly recommended to all who might be called upon to treat hand injuries, and should be required reading for those in surgical training whose specialty involves the hand, namely the plastic surgeon, neurosurgeon, general surgeon, and certainly the orthopedist. —STIRLING J. RITCHIE, COL. USA

THE CLINICAL PSYCHOLOGIST by William A. Hunt, Ph.D. 206 pages  
Charles C. Thomas, Publisher, Springfield, Ill., 1956. Price \$5.50

The author is chairman of the department of psychology and lecturer in psychiatry at the medical school of Northwestern University. He is thus adequately prepared to discuss the main theme of his subject, namely the relationship between medicine and psychology. Without mincing words he lays bare the central problem of psychologic practice: namely, should the qualified clinical psychologist do psychotherapy?

By exploring definitions and by giving a careful analysis of the problem the author has made a major contribution. Most clinical psychologists are seriously occupied with this problem, and the book is believed to be essential reading for all of these. Students who plan to enter the field of clinical psychology should be interested in reading Dr. Hunt's point of view because their appraisal of a career in psychology may be inadequate without this realistic reminder of the presence of controversies in the field—controversies about which not much is said in the classrooms. Above all, psychiatrists, psychoanalysts, physicians, and social workers will find the volume helpful in understanding the clinical psychologist and his approach to his work.

Besides the major emphasis, the book describes the training of clinical psychologists and mentions the commonly used psychologic techniques. Some psychologists would not agree with the author's remarks on Freud. Nor would all psychologists agree on the role Dr. Hunt has assigned to diagnostic testing in the evaluation of the clinical psychologist's work. This book is worth reading by all those interested in mental health, although the thoughtful reader will not always agree with the author. —THEODORF C. KAHN, Maj. USAF (MCG)

THE MANAGEMENT OF MENSTRUAL DISORDERS by C. Frederic Fluhmann, M.D.C.M. 350 pages, illustrated. W.B. Saunders Co., Philadelphia, Pa. 1956. Price \$8.50

In this volume Dr. Fluhmann has succeeded in presenting an oft-misunderstood subject in a clear, direct manner that should help both the practitioner and student in handling the many patients who present themselves for the care and treatment of menstrual disorders.

Controversial problems are covered in such a way as to inform the reader of the various viewpoints, allowing him to form his own impression.

sion and enabling him to follow up the particular subject by presenting a fairly complete well selected list of references in the bibliography at the end of each chapter. The role of the gonadotrophic and steroid hormones in menstruation is discussed in an easy manner conducive to sound understanding of the role they play in initiating and discontinuing the menstrual function.

The last chapter is an up to the minute review of modern day clinical usage of the sex hormones with a well outlined presentation of the numerous leading commercial preparations that stresses the routes of administration usual accepted dosage levels and the products trade name and manufacturer —MORRIS M. RUBIN *Capt MC USA*

CLINICAL EXAMINATIONS IN NEUROLOGY by Members of the Section of Neurology and Section of Physiology Mayo Clinic and Mayo Foundation for Medical Education and Research Graduate School University of Minnesota Rochester Minn 370 pages illustrated W B Saunders Co Philadelphia Pa 1956

This book deals with the systematic presentation of neurologic examination as practiced by the members of the sections of neurology at the Mayo clinic. The compilation of a book on the neurologic examination is extremely difficult as many tests that are included in the examination by some neurologists are preferred to others which are sometimes better known. Nevertheless in this work the reviewer feels that the authors have done an outstanding job in selecting the most significant methods of testing for manifestations of neurologic dysfunction. This book is not intended to be an esoteric chronicle of the more obscure manifestations but rather a practical guide to the student to the intern and to the beginner in neurology interested in learning convenient office procedures which will aid in the evaluation of neurologic conditions. In this respect this book is outstanding.

The authors have selected tests concerning which there is general agreement among most neurologists as to their value. The methods are briefly and concisely explained and are augmented by statements as to the functional significance of the normal or abnormal manifestations. The authors have taken great pains to eliminate controversial material and have done a very skillful job of editing this volume. While it offers little that is new to the specialist there are few specialists who would not feel that a perusal of the volume was a rewarding experience representing as it does an orderly treatise on the neurological examination. Only a very few adverse criticisms can be leveled at the work. Perhaps one might be the numerical gradation of reflex activity and of sensory response in the clinical neurologic examination.

This volume is recommended to the practicing physician who maintains an interest in neurologic conditions and to residents or fellows undergoing training in the specialty of neurology.

—ROY E. CLAUSEN *Jt Col MC USA*

March 1957)

**CHEMOSURGERY IN CANCER: GANGRENE AND INFECTIONS** featuring a New Method for the Microscopically Controlled Excision of Cancer, by Frederic E. Mohr, B. Sc. M. D. 305 pages illustrated Charles C. Thomas Publisher Springfield Ill. 1956 Price \$13.50

This monograph represents 25 years' experience by a singularly zealous worker. Almost single handedly he has fostered the development of this very controversial method of cancer treatment. The method which he calls chemosurgery consists of chemical fixation of the tumor in situ with zinc chloride solution and staged surgical excision with repeated microscopic examinations of the tissue in the bed of the lesion to assure complete removal.

The caustic treatment of neoplasms goes back to antiquity. In the last century many quacks in this country were infamous for their misuse of caustics in cancer. However, Doctor Mohr's real contribution, which removes his technique from such a class, is his histologic control of the process. He has developed considerable skill in hisologic technique. Frozen tissues are studied right in the clinic upon removal in order that the proper orientation of the sections can be made. The microscopic extension of cancer beyond its grossly visible or palpable extent can then be studied.

His wide application of the method is well documented by numerous excellent photographs, case histories and end result statistics. In addition to squamous and basal cell carcinoma of the skin, he treats carcinoma of the lip, accessory nasal sinuses, larynx, parotid, penis, vulva, et cetera. Perhaps most controversial is his chemical cautery treatment of melanomas and pigmented nevi. Here again his results have been excellent.

The author has published numerous papers containing much of the material in the book. His material is presented precisely and quite convincingly. One wishes that such ability, high motivation and sincerity could be devoted to a more challenging aspect of cancer therapy.

This book will be of value for medical libraries as a definitive work in this limited field. —ROALON GRANT, Capt. MC USA

**CLINICAL ROENTGENOLOGY** Volume IV The Digestive Tract, the Gall Bladder, Liver and Pancreas, the Excretory Tract and Special Studies Emphasizing Differential Considerations by Alfred A. deLoraine, M. D., Henry G. Moehring, M. D. and John R. Hannan, M. D. 764 pages 112 illustrations Charles C. Thomas Publisher Springfield Ill., 1956. Price \$24.50

This readable, clear, concise and beautifully illustrated volume is a worthy contribution to the literature. It is not designed for detailed study but rather for quick, balanced reference. If one desires to pursue any subject further, an adequate bibliography is provided at the close of each chapter.

The volume is free of padding or extraneous material and the approach to each subject is objective and concrete. The illustrations are superior reproductions of original radiograms with ample specific annotations. The brief but accurate references to embryology, anatomy and physiology serve to refresh the reader's memory with the application of these basic sciences to the pathologic condition under consideration.

In reviewing a book so replete with information it is difficult to appraise critically one section against another. Those sections dealing with the digestive and excretory tracts are impressive.

One of the most valuable aspects of this book is the frequent reference to differential diagnosis with the clinical and laboratory relationships. The choice of the title *Clinical Roentgenology* is good for no work has emphasized more clearly the role of the radiologist as a practicing physician.—ALLAN B. RAMSAY, Col MC, USA

**ATHLETIC INJURIES** Prevention, Diagnosis and Treatment by Augustus Thorndike M.D. 4th edition. 252 pages. 113 illustrations. Lea & Febiger Philadelphia Pa. 1956. Price \$4.50.

The purpose of this small monograph is to present the problem of the prevention, diagnosis and treatment of injuries received in American college sport. This edition includes new drawings to elucidate the technique of applying supportive strappings and bandages.

The first section of the book contains an interesting historical resume of the origin of medical supervision of college athletics and its results with a discussion on physical fitness and fatigue. The second section deals with the different types of trauma and their treatment. The author states "This chapter will not go into detail as to the proper methods of fracture therapy as many textbooks cover this field adequately." This applies equally to his discussion of other types of treatment which might be appropriately included in the preface. He does emphasize the necessity of open reduction of ankle fractures whenever restoration of the joint to normal cannot be accomplished by conservative methods.

The third section deals with each anatomical region and is probably intended as a reference. The author's thoughts on knee injuries are at variance with those of many others. Tabulating 356 injuries to the medial collateral ligament alone, he enumerates only nine cases in which such an injury was combined with injury to the anterior cruciate. His treatment of knee ligament sprains rightly emphasizes the prevention of quadriceps atrophy but denies the efficacy of plaster fixation or operation except in severe cases. However, he admits that cases treated in this manner always have a residual laxity of the ligament.

The illustrations of the techniques of applying supportive strappings are well done and lucid.—WILLIAM S. STRYKER, Capt MC, USN

**THE INITIAL MANAGEMENT OF THORACIC AND THORACO-ABDOMINAL TRAUMA** by *Laurence M. Skeets M D* A Monograph in The Bannertone Division of American Lectures in Surgery edited by *Michael E. DeBakey M D* and *R. Glen Spurling M D* Thoracic Surgery Division Editor *Brian B. Blades M D* 121 pages illustrated Charles C Thomas Publisher, Springfield Ill 1956. Price \$6.50

This short, well written monograph of 121 pages contains most of the essentials required for the management of thoracic and thoraco-abdominal trauma. The author, in addition to his vast personal experience in this field has quoted other equally experienced surgeons.

Particularly stimulating is the author's emphasis on adequate resuscitation before any ill advised major surgery is undertaken. Many such cases having been adequately resuscitated are found not to require operative interference. Along this line Dr Churchill's remarks in the foreword are very apropos concerning "panic decisions" and "stairpedes to the operating room" as well as "trigger happy surgeons".

The book is well illustrated and indexed. It is simply written in a concise manner appealing to the reader. As an excellent easily understood, quick reference on resuscitative rather than operative measures it should be available to all military medical officers and civilian physicians, particularly those who may be called upon to treat mass casualties. —**SANFORD W. FRENCH III Col MC USA**

**ROENTGEN SIGNS IN CLINICAL DIAGNOSIS** by *Isadore Meschan, M. A. M. D.* with the assistance of *R. M. F. Farrer-Meschan M. B. B. S.* 1 058 pages 2 216 illustrations on 780 figures W. B. Saunders Co Philadelphia Pa 1956. Price \$20

This text is written for medical students residents in radiology and practicing physicians. It presents the fundamentals of radiology rearranged on the basis of objective signs as seen in roentgenograms. The text is so organized that the limitations and accuracy in roentgen diagnosis are pointed up by demonstrating the technical and anatomic facets behind roentgen signs. It is organized to lead the reader to systematic thinking and analysis of roentgen signs prior to the formation of definitive diagnoses. The author uses this book along with his *Atlas of Normal Radiographic Anatomy* in his teaching of radiology.

There are hundreds of excellent roentgenograms and numerous line drawings point out details in the roentgenograms. References are kept to a minimum of key articles which will provide addition. Many of the chapters begin with an annotated review covered in the chapter. Since the author is a radiologist, in his field of radiology he must necessarily be an expert.

The book is easy to read concise and clear. It is a must for all radiology trainees and it will be a valuable addition to the radiologist's library. —**JOHN L. HATCH Col MC USA**

THE TREATMENT OF FRACTURES by Lorenz Böhler M D Volume I translated from the Thirteenth German Edition by Hans Teller Helen B Luchini Frank Kreuz Otto A Russe and Robert G B Bjornson 5th edition in English 1 072 pages 1 721 illustrations Grune & Stratton Inc New York N Y 1956 Price \$24 50

This monumental treatise which represents the first of three volumes follows the form used in previous editions on treatment equipment and reasons for failure While there is a considerable expansion of text and in x ray prints which are pertinent and clear examples of points discussed illustrations are often widely separated from the explanatory text

Approximately 280 pages are devoted to a general discussion of the treatment of trauma to soft and bony tissue There is discussed the organization of a fracture service and the x ray requirements and also a detailed discussion of essential pieces of apparatus, splints and special devices for treatment of fractures

There are many clear illustrations of excellent results obtained in the treatment of severe and complicated injuries of the extremities The discussion of fractures of the forearm is excellent however such statements as medullary nails should not be used will hardly be widely agreed with in this country at present Also the use of the Böhler clavicular "block splint as well as some of the devices for abduction treatment of upper extremity injuries although no doubt successful are not likely to become popular in American orthopedic practice

It is still felt by this reviewer that Doctor Böhler's greatest contributions to orthopedic practice are his valuable fundamental principles which are again frequently reiterated throughout the book as in previous editions 1) Slight shortening (over-riding) should always be the goal in order to insure union 2) Closed (simple) fractures should be treated by meticulous closed reduction avoiding open reduction unless critically necessary 3) Insertion of foreign bodies such as metallic fixation devices and unnecessary sutures should be avoided and skin only should be sutured in open (compound) fractures

The most serious criticism of this work is that throughout the book there is considerable repetition of statistics and experiences from the pre antibiotic period extending as far back as 1914 Granting that there is value in comparing treatment in that period with that at present it could be more appropriately condensed into a single short chapter for convenient reference

If one is a complete disciple of Böhler he will find much to delight him and little to criticize in this volume —WALTER R MILLER Capt MC USN

## New Books Received

Books received by the *U S Armed Forces Medical Journal* are acknowledged in this department. Those of greatest interest will be selected for review in a later issue.

## Monthly Message

In November 1956 a two day meeting of the Joint Committee on Aviation Pathology was held with an attendance of over 100 military and civilian scientists, engineers and pathologists from the United States the United Kingdom and Canada

In a study of almost 300 gross autopsy reports it was demonstrated that fatal head injuries incurred in accidents during landing and takeoff procedures were often the only significant pathologic changes noted. This emphasizes a pathway of further study along preventive lines.

Study of the degree and location of burns is often most helpful to engineers and materiel experts in arriving, as to where the fire originated its intensity and duration.

A study of pathologic findings of 14 cases of death due to inflight decompression sickness demonstrated the need for further experimental work in this direction. Other developments centered about (1) the possibility of use of ultraviolet fluorescence and a potential role of infrared in the use of the electron microscope (2) studies in explosive decompression at high altitudes (3) attempts to devise a test on post mortem tissues to show the existence of ante mortem hypoxia (4) problems concerned with toxicology carbon dioxide fuels et cetera and (5) hyperventilation and hypoglycemia and pre existing disease.

These are some of the paths in research which come within the purview of this Committee in its important contribution to the prevention of airplane accidents.

## Foreword

The *United States Armed Forces Medical Journal* is the medium for disseminating information of administrative and professional interest to all medical personnel of the Department of Defense. The Assistant Secretary of Defense (Health and Medical) and the Surgeon General of the several services invite all medical officers, dental officers, Medical Service Corps officers, Nurse Corps officers, and officers of the Veterinary Corps of the Armed Forces, and the medical consultants of the Army, Navy, and Air Force to submit manuscripts for publication in this journal.

## TREATMENT OF PNEUMOMEDIASTINUM WITH INCREASED AIR PRESSURE

JOHN H. SCHULTE *Lieutenant Commander MC USA*

**P**NEUMOMEDIASTINUM was first described in 1819 by Lennec.<sup>1</sup> Since that time there has been a continual increase in knowledge concerning the pathogenesis, signs, symptoms, and differential diagnosis, but little advancement in the treatment of this condition. This article reports two cases of pneumomediastinum that were treated successfully with increased ambient air pressure, a method which has not been previously described in the literature for the treatment of this condition.

### PATHOGENESIS

Air may gain access into the mediastinum by one of five avenues: (1) directly into the mediastinum from perforation or surgical procedures on the upper respiratory system and esophagus, (2) dissection of air from the deep fascial planes of the neck, (3) dissection of air from the retroperitoneal space, (4) rupture of the alveoli into the pulmonary interstitial tissue, and (5) dissection of air from the deep fascial planes of the anterior abdominal wall during pneumoperitoneum.<sup>2</sup>

### SYMPTOMATOLOGY

The onset of symptoms varies from a few minutes to a few days. This may be of importance in the differential diagnosis from air embolism which is usually immediate. The development of convulsions, which may occur in air embolism, has never to my knowledge been reported in a case of pneumomediastinum.

From U. S. Naval Medical Research Laboratory, U. S. Naval Submarine Base, Groton, Conn. Comdr. Schulte is now at Pittsburgh Area Field Office, Atomic Energy Commission, Idaho Falls, Idaho.

The usual symptoms in this condition are substernal distress or fullness, sore throat, hoarseness, dysphagia, choking sensations, dyspnea, and varying degrees of respiratory embarrassment.

The physical examination may reveal cyanosis and subcutaneous emphysema of the neck, chest wall, and the abdomen. A tympanic percussion note may replace the normal substernal dullness. Distant heart sounds and a crunching sound synchronous with the heart beat (Hamman's sign) have been noted.

Roentgenograms of the chest reveal the presence of air in the fascial planes and in the mediastinum, especially in the oblique and lateral views. This may extend into the neck and be demonstrated in the roentgenograms of the neck. No characteristic electrocardiographic pattern is produced by pneumomediastinum.

### TREATMENT

Treatment has consisted of observation, bed rest, and symptomatic therapy in mild cases, with gradual resorption of the gas over a period of several days. In more severe cases, needle aspiration or catheterization and suction through the suprasternal notch or an intercostal space have been attempted to remove the excess gas from the tissue spaces.

### CASE REPORTS

**Case 1** A 25 year-old man began taking the routine pressure test in the recompression chamber as a preliminary part of his submarine escape training. During the application of pressure he experienced a great deal of difficulty equalizing the pressure in his middle ears.

The instructor in the chamber noticed that he used the Valsalva maneuver to maintain ear equalization and advised the man against using excessive force. The instructor stopped increasing pressure several times to allow the man to regain his equalization.

The required pressure (50 lb/sq in indicated gage pressure or 64.7 lb/sq in absolute pressure) was reached in seven and one half minutes. The man experienced no further difficulty and the pressure was released at the normal rate of 12 lb/sq in /min. Upon return to sea level pressure the man complained of pain in both ears, tinnitus, and soreness of the neck muscles.

Physical examination revealed crepitation in the anterior cervical triangles and a grade 3 acrotitis medii (Teed's classification) bilaterally. No other physical abnormalities were found.

The patient was put at bed rest under observation. Four hours later his symptoms had subsided and he was allowed to return to his home. He was instructed to call the escape training tank officer immediately upon any change in his condition.

Early the same evening he called the training tank officer complaining of soreness in the neck, difficulty in breathing, tightness in the chest, and inability to swallow anything other than liquids. He also noticed that his voice had become deeper in pitch. He stated that the symptoms had developed slowly and progressively since leaving the pressure chamber that morning.

Upon physical examination he appeared moderately apprehensive but in no acute distress. His blood pressure was 110/95 mm Hg, pulse 120

*Figure 1 (case 1) Posteroanterior view of the chest demonstrating free air in the mediastinum and extending into the neck.*

weak, slightly irregular, and thready, and respiration rapid and shallow. There was palpable crepitation throughout both anterior cervical triangles. The ears revealed a grade 3 aerotitis media bilaterally. There was minimal injection of the posterior pharynx. Examination of the chest

revealed normal lung fields. The precordium and the mediastinum were tympanic to percussion. Heart sounds were irregular and distant becoming inaudible when the patient leaned forward. Roentgenograms revealed air in the mediastinum and extending into the neck (figs 1 and 2).

The man was placed in the recompression chamber and pressure treatment was begun. At 14 lb/sq in indicated gage pressure he stated the tightness in his chest was somewhat relieved. Physical examination revealed no appreciable change in the physical findings.

Figure 2 (case 1) Oblique view of the chest. Note large bubble of air in the subcutaneous tissue over the left clavicle.

Recompression was continued until 44.5 lb/sq in indicated gage pressure was reached. The patient stated that he had complete relief of symptoms. His voice had returned to its normal pitch.

Physical examination revealed a blood pressure of 125/65 mm Hg and a regular pulse with a rate of 92/min. Percussion of the chest revealed

normal mediastinal and precordial dullness. The heart sounds were good and regular. Some crepitation still persisted in the neck.

Recompression was continued to 75 lb/sq. in indicated gage pressure and treatment in accordance with Navy treatment tables begun. Upon reaching atmospheric pressure (0 lb/sq. in gage pressure) approximately 20 hours later, the man was completely asymptomatic except for some muscle soreness in the anterior neck muscles. Physical examination was negative except for a slight amount of crepitus over the

*Figure 3 (case 1) Posteroanterior view of the chest immediately after treatment showing complete resorption of the air in the tissues*

sternocleidomastoid muscles. He was transferred to the infirmary for 24 hours' observation.

Upon discharge from the infirmary he was asymptomatic. Physical examination was completely negative. Roentgenograms of the chest and

neck revealed complete resorption of gas and an electrocardiogram revealed no evidence of cardiac damage (fig 3)

Case 2 A 24 year old man developed mild chest pain while making simulated submarine "free" escapes from depths of 18 and 50 feet (8 and 14 lb/sq in gage pressures respectively) in the submarine escape training tank

During the afternoon the discomfort continued but did not incapacitate him from playing a round of golf By evening the man noted substernal fullness mild dyspnea dysphagia hoarseness deepening of the voice and pain in the neck on motion in any direction

Figure 4 (case 2) Lateral view of the neck showing a mass in the posterior pharyngeal wall extending into the superior mediastinum

Physical examination revealed a white male of stated age in no apparent distress. His blood pressure was 110/75 mm Hg, pulse, 72 full and regular, respiration, 20/min, and somewhat cogwheel.

There was resistance and pain in the neck on movement of the head. A small area of crepitation was noted at the medial edge of the right sternocleidomastoid muscle. There was moderate congestion of the nasal mucosa, posterior pharynx, larynx, vocal cords, and epiglottis. The chest was clear to palpation, percussion, and auscultation. Roentgenograms revealed air in the retropharyngeal space extending into the mediastinum (fig. 4).

The man was placed in the recompression chamber and pressure treatment was begun. Upon reaching 75 lb/sq in gage pressure the patient was completely relieved of his symptoms and his voice had returned to normal. The crepitus noted on previous physical examination had completely disappeared. There was no limitation of motion in the head or neck. Treatment was carried out in accordance with the standard Navy treatment tables.<sup>5</sup>

After completion of treatment the man remained asymptomatic and physical examination was completely negative. He was transferred to the infirmary for observation. Twenty-four hours later he was returned to duty. Roentgenograms of the chest and neck demonstrated complete resorption of the air.

### DISCUSSION

Rupture of the alveoli allowing air to enter the pulmonary interstitial tissue is the probable cause for the development of pneumomediastinum in both of these men.

The first man ruptured his alveoli by using the Valsalva maneuver too forcefully while attempting to equalize pressure in his middle ears during a pressure test. The second man apparently allowed the air pressure in his chest to exceed the outside water pressure while ascending through the water when making simulated submarine escapes.

Peabody and Buechner<sup>2</sup> demonstrated in dogs that rupture of the alveoli allowed air to dissect along the perivascular and peribronchial interstitial tissue into the mediastinum. The air entered the interstitial tissue during inspiration and was slowly milked toward the mediastinum during expiration. This explains the gradual onset and progressive increase in symptoms typical of this type of pneumomediastinum.

The use of increased ambient air pressure is standard practice in decompression sickness (bends) and in air embolism in divers.<sup>6,7</sup> The rationale for using increased pressure is that bubbles in tissues will be more rapidly reduced in size.

plication of 75 lb/sq in gage pressure (6 atmospheres absolute) reduces the size of a gas bubble to one sixth its original volume thus allowing a more rapid reabsorption of gas into the body fluids and elimination through the lungs

The interstitial gas bubble in the mediastinum will respond to increased pressure in the same manner as the intracellular gas bubbles of decompression sickness or the intravascular gas bubbles of air embolism. It can therefore be expected that pneumomediastinum will respond well to this form of therapy

#### SUMMARY

The treatment of pneumomediastinum has in the past been primarily symptomatic. In severe cases attempts were made to aspirate the air through the suprasternal notch or an intercostal space.

Two patients with clinical and roentgenologic evidence of pneumomediastinum who were treated by exposing them to increased ambient air pressure which was then gradually reduced made rapid and complete recoveries. One patient had developed the pneumomediastinum when he performed a forceful Valsalva maneuver while being subjected to a routine pressure test in the recompression chamber as a part of his submarine escape training. The other patient had developed it while making simulated "free" escapes in the submarine escape training tank.

This method of treating pneumomediastinum has not been reported previously in literature. Its degree of success and the rate of recovery are far superior to results obtained with older for

# SERIOUS HEART DISEASE SIMULATED BY HIATUS HERNIA

EDDY D PALMER *Lieutenant Colonel MC USA*

**D**URING management of 214 patients with the direct or "sliding" type of hiatus hernia, 11 were encountered who presented the classical symptoms of angina pectoris and three who showed the classical manifestations of acute myocardial infarction. Several other patients with more complicated clinical pictures had complaints that suggested coronary artery disease in addition to various forms of dyspepsia.

The problem which patients of this category create concerns much more than mere differentiation of heart disease from hiatus hernia. Some patients clearly have both, without apparent causal association, as did nine of the 214. Others appear to show significant coronary artery repercussions resulting from some form of autonomic reflex sparked by the activities of the displaced gastric sac. It has not been possible to date to define the degree of influence that the one organ may have over the other during various physiologic and pathophysiologic activities, because animal experiments are clearly not applicable to the human and because among humans there appears to be a very wide individual variation in coronary artery response to visceral stimulation.

The present report is concerned only with clinical differentiation of heart disease from hiatus hernia. The importance of the differentiation needs no emphasis, but it is worth noting that the 11 patients who had been carrying the diagnosis of coronary insufficiency had been needlessly living the restricted and frightened lives of angina pectoris patients for an average of more than eight months. Following are brief reports on a typical case of hiatus hernia mimicking coronary insufficiency and on the three instances of misdiagnosed infarction.

## CASE REPORTS

**Case 1** This 45 year old medical officer was engaged in moving heavy equipment during the invasion of Normandy in 1944 when he was seized by a constricting pain deep in the chest with aching radiation down

---

From 2d General Hospital, APO 180 New York N Y

his left arm. An electrocardiogram made five hours later was found to be normal and he returned to his arduous duties. He was in active combat for a month before he was studied in any detail. Meanwhile he had four recurrences either during physical strain or during meals. Detailed cardiac studies were normal but a small hiatus hernia was discovered. The diagnosis of coronary insufficiency was nevertheless made, and he was eventually separated from the Army by disability retirement. During the next three years he had many recurrences of the same type of pain lasting 2 to 10 minutes at a time and clearing spontaneously with rest. He found that on only some occasions would prescribed nitroglycerin help. Three times he vomited small amounts of bright blood, this being the only overt gastro-intestinal symptom. Hospitalization and restudy on three further occasions led to confirmation of the diagnosis of coronary insufficiency. Now upon the current hospitalization the cardiologist was not able to find any heart disease nor from the previous records could he confirm the previous diagnosis. A hiatus hernia was again found roentgenologically and esophagogoscopic examination showed moderate subacute erosive esophagitis. The esophagogastric junction lay 2 cm proximal to the hiatus. The hernia was repaired surgically. During the 15 month follow-up period there were no further pain recurrences.

**Case 2.** This 54 year-old white man previously well was awakened one night by a severe crushing pain over the middle of the chest anteriorly. It cleared spontaneously after about two minutes but during the next morning it returned four times while he was at rest becoming progressively more sustained. It was accompanied by a smothering sensation. He was hospitalized with the diagnosis of myocardial infarction. Physical examination revealed a frightened patient who was sweating and exhibiting moderate tachycardia. There was no cyanosis and the respirations were quiet and easy. The blood pressure, heart, lungs, and abdomen appeared to be normal. Subsequent studies showed repeatedly normal electrocardiograms, sedimentation rate, white blood cell count, roentgenograms of the chest, and temperature. Contrast fluoroscopy revealed a small direct hiatus hernia and esophagoscopic study confirmed the diagnosis and demonstrated complicating erosive esophagitis. Medical management was decided upon for the moment but because of a recurrence two months later surgical repair was accomplished. Reevaluation 13 months later showed that there had been no further pain or other complaint.

**Case 3.** During a period of 13 years this 43 year old white man had six episodes of bursting epigastric pain rising through the chest to the neck, jaw, eyes, shoulders, and arms. On two occasions the pain had been accompanied by sweating, hypotension, unconsciousness, and incontinence. The attacks had appeared in an entirely unpredictable fashion without relationship to any activity. They lasted from one half to two hours. The patient had been hospitalized on each occasion and treated at the outset as a case of myocardial infarction.

Some of the records were available now during the current hospitalization. The long series of electrocardiograms showed no abnormalities except for temporary ischemic changes over a five day period three years previously. A 2 cm hiatus hernia had been demonstrated on two occasions. Surgical correction was now recommended but the patient would accept no more than a trial phrenic crush, having been convinced that he had serious heart disease. After three asymptomatic months, he thought that the point had been proved and underwent hiatal repair.

**Case 4.** This 64 year-old hypertensive woman who had complained of pyrosis for several years was awakened one night by severe heavy substernal and epigastric pain. She felt as though she were being smothered and found it difficult to get her breath. Because she lived alone, she was not able to get help. Upon attempting to rise she fainted briefly and broke out in a cold sweat. After seven hours the pain gradually went away and she was able to go to the hospital. The history revealed two previous spells of similar but briefer and milder pain during the previous five months. The second time she was hospitalized for six weeks and discharged with the diagnosis of myocardial infarction. Admission examination now revealed only fear, tiredness and moderate hypertension. All routine and special cardiac studies were otherwise normal but a small hiatus hernia was found by roentgenographic and esophagoscopic study. The hernia was repaired surgically. Postal reports to the present 21 months later have indicated that there has been no further pain.

#### COMMENT

It is not being suggested that it is an onerous matter to avoid mistakes like this but rather that, because not all substernal pain is heart pain, failure of objective studies to confirm the clinical impression of heart disease necessitates reevaluation of the whole problem. The most disturbing attitude to be found in this situation is that the most serious possible diagnosis must be accepted as the working diagnosis because of the potential consequences of an error in the other direction. Much depends, quite naturally, on the clinician's individual subspecialty orientation or his special interests. The previous clinical records of the present group of patients contained many references to the clinician's insecurity over the normal or slightly abnormal electrocardiographic and other studies. Often this was covered by a statement to the effect that the best cardiologic teachings indicate that electrocardiographic abnormalities do not always occur in instances of overt coronary artery disease, even when there is infarction, and that, regardless, the clinical impression must take precedence over objective testing methods. A substantial misleading factor in the cases of "angina pectoris" was the therapeutic test of symptomatic response to nitroglycerin. It

appears to be a poorly recognized fact that the pain of hiatus hernia, as well as that of several types of esophageal dyskinesia responds rather well to the nitrites. No comfort regarding the diagnosis of coronary insufficiency should be taken from the results of such a therapeutic regimen.

One of the important considerations in all dealings with the symptomatology of hiatus hernia is that, as a rule, the smaller a hiatus hernia is the more severe are the subjective manifestations. The hernias among the present group of 14 patients were 2 to 3 cm in extent but no larger. The hernias in some of the other patients in the whole series were very much larger but among them the symptoms included no sudden or severe pains. Quite naturally, the smaller a hiatus hernia is the more difficult the diagnosis is to establish—and the more difficult it is to convince one's surgical colleagues that repair is indicated.

It is an important error to assume that a normal upper gastrointestinal x ray series excludes the diagnosis of hiatus hernia. Not only must the radiologist use special techniques if he is to demonstrate the lesion but also in many cases the herniation is an intermittent affair spontaneously undergoing reduction which cannot be quickly reproduced on the fluoroscopy table. Among the 214 cases, a single roentgenographic series demonstrated the lesion in only 78 per cent and repeated studies in only 85 per cent. The results of esophagoscopy were a little better the figures being 85 and 88 per cent respectively but the important point is that both examination techniques are required before the possibility of hiatus hernia can reasonably be excluded.

#### SUMMARY AND CONCLUSION

Seven per cent of 214 patients with direct hiatus hernia presented the classical symptomatology of either coronary artery insufficiency or myocardial infarction and were treated for variable periods of time as cardiac patients. The most important error involved in addition to lack of awareness over the cardiac mimicking potentialities of hiatus hernia, was failure to accept the normal results of objective studies because the clinical features of heart disease seemed so evident. Hiatus hernia is not always an easy diagnosis to establish, and this is an especially important consideration when it comes to differentiation from coronary artery disease for the smaller a hiatus hernia is the more likely it is to cause severe chest pain.

# BILIARY RADIOMANOMETRY

MAX L. SMITH *Lieutenant Colonel MC USA*

MANUEL SANTOS M D

**B**ILIARY radiomanometry is really a refinement of cholangiography. It is a diagnostic technic in which pressure readings and contrast roentgen studies are done simultaneously. Both of these technics have been used separately for a long time, but it is their rather recent combination into one study that makes the technic more valuable.

Since the days of Oddi,<sup>1</sup> manometric studies have been made in which water, bile, and mercury were used as perfusing agents. These have contributed greatly to our knowledge of the physiology of the biliary tracts. Mirizzi<sup>2,3</sup> proposed the use of routine operative cholangiography. This simple method gives excellent morphologic images of the bile ducts, but there may be abnormalities of the two sphincter areas which are not detectable by the hand or eye of the surgeon or by a single picture of the bile ducts which have been filled with opaque liquid. These abnormalities can only be detected by the slight variations of pressure which are necessary to permit fluid to pass these zones.

During the past 25 years of the more or less widespread use of cholangiography, the results of biliary surgery have failed to be entirely satisfactory. Great emphasis has been placed on the detection of stones, but the functional and the combined functional organic disorders of the biliary apparatus have remained largely unsolved. Many studies of the late results after biliary surgery indicate the need for a better diagnostic method, both preoperatively and during surgical intervention.

Sendwiese and Fulton,<sup>4</sup> in analyzing a series of patients who had undergone cholecystectomy for cholelithiasis, found moderate to severe symptoms persisting in 10 to 25 per cent. When the procedure was carried out for the noncalculous gallbladder, the number of patients having symptoms increased to 50 per cent. Schildt<sup>5</sup> reviewed a group of 500 patients who underwent biliary surgery between 1950 and 1952 and found that only 70 per cent were symptom free. In 1952, Coleman and Bonnett<sup>6</sup> found 68 occurrences of symptoms in 487 cholecystectomies.

---

From Walter Reed Army Hospital, Washington, D. C. Dr. Santos was Official Observer at this hospital from Universidad de Chile (Catedra Prof. Velasco S.).

Reports after surgery on the common duct also indicate that there is a need for better diagnosis and treatment. Preston and Alden<sup>7</sup> analyzed 74 postoperative cholangiograms made through an indwelling T tube after common duct surgery and found normal common ducts in only 56.7 per cent, stones in the common duct in 24.3 per cent, and partial or complete obstruction of the distal third of the common duct in the remaining 19 per cent. The reported incidence of residual common duct calculi ranges from 2 to 33 per cent.<sup>8</sup>

Biliary radiomanometry fills some gaps in the interpretation of the roentgen films taken without fluoroscopy, because the curves of biliary pressures obtained give information which is in many ways equivalent to that found on a fluoroscopic examination.

Caroli and Maurv<sup>9</sup> in 1937 were the first to use this combined technic in which multiple views of the dye-filled biliary ducts were taken at different pressures. This technic has been varied and perfected by numerous surgeons abroad, particularly by Mallet Guy,<sup>10</sup> Albot, Olivier, and Libaudo<sup>11</sup> and Kapandji.<sup>12</sup>

The principle of this technic is simple and consists of a graduated glass tube manometer being connected to a source of radiopaque dye and to the patient's biliary tree, either the gallbladder or the common duct. This apparatus, together with conveniently arranged x-ray equipment, is designed to take several views of the biliary system while the radiopaque material runs from the perfusion system under controlled pressures.

#### APPARATUS AND METHODS

The apparatus we use is similar to that described by Jacques Caroli<sup>13</sup> (fig. 1). It consists of a glass flask of approximately 150 ml capacity which contains the contrast media. This flask is connected to a 20-ml syringe which contains a constant level of fluid in the syringe, irrespective of the rate of perfusion. Thirty-five per cent Diodrast solution (brand of iodopyracet) may be used as the contrast media. The syringe is connected to a glass manometer and to the patient's biliary tract by a Y tube. The perfusing system, consisting of the glass flask and the syringe, is held rigidly together and can be raised or lowered as the pressure is increased or decreased. The glass tube manometer should be approximately 75 cm long and 8 mm in diameter. The centimeter markings should be clearly visible for a distance of several feet. The apparatus may be connected to a kymograph to permit the recording on a graph of the variations of pressures during the exploration.

The rubber tubing connecting the various parts of the apparatus should be heavy enough to prevent kinking and have at least an 8 mm diameter to prevent significant capillary action. A zero point on the patient is established at the level of the biliary ducts. For

*Figure 1 Manometric apparatus in use in the operating room.*

practical purposes this may be considered to be midway in the trunk between the anterior and posterior abdominal walls. Zero point on the manometer and the fluid level in the syringe of the perfusing apparatus must be brought to the same level of the bile duct being investigated before beginning the study. All air bubbles should be removed from the tubing before the studies are begun to avoid producing radiolucent defects in the bile ducts (fig 2). If the gallbladder is being studied, it is most convenient to introduce a corrugated needle which can be tied in position with a purse string suture. If the common duct is being investigated, it is convenient to introduce through the cystic duct a curved cannula similar to the one devised by Mallot Guy (fig 3). In the absence of these two pieces of apparatus, other types of catheter or plastic tubing may be used.

The use of morphine preoperatively should be avoided. The patient is placed on a flat box on the operating table, and general anesthesia given. The box has an opening at the head of the table through which the cassettes can be very readily positioned and removed. This avoids the necessity for getting under the drapes for each x-ray exposure. A scout film is taken to check the position of the cassette and the quality of the film before surgical intervention is begun. The radiomanometric study should be done with minimal manipulation of the biliary tree.

Biliary manometry of the gallbladder is only worthwhile when no obvious pathologic disorder is found on inspection or palpation.

Figure 2. Establishing the zero point

of the gallbladder. In the presence of gross pathologic disease in the gallbladder the cystic duct should be exposed and cannulated for a study of the common duct before the gallbladder is removed.

#### PRESSURE DETERMINATIONS

The first pressure to be determined in the gallbladder is the *initial intracavitary pressure* which represents the hydrostatic pressure present in the biliary system before any interference. With the apparatus at zero level the cannula is inserted without spilling bile. The perfusion system is clamped off. Bile will be seen in the transparent system leading from the gallbladder, and the rise in the fluid level in the manometer is noted. This intracavitary pressure in the gallbladder is normally about 6 to 8 cm of Diodrast. The determination of this pressure is important in order to compare it with the pressure necessary to open the sphincter mechanism. When studying intracavitary pressure in the common duct a special needle which can be inserted directly into the duct without spilling the bile is needed (fig. 4).

*Figure 3 Mallet Guy's cannula for use through the cystic duct and his needle for direct puncture of the gallbladder*

*Figure 4 Determining the intracavitary pressure*

At this point in the procedure, the tube leading from the perfusing syringe is opened and the apparatus is raised a few centimeters at a time to determine the pressure required to open the sphincter. The tube is clamped after every elevation. At a certain point the fluid level in the manometer will suddenly drop indicating that the dye has passed through the cystic duct, if the gall bladder is being studied, or through the sphincter of Oddi, if the common duct is being studied. This is called the *transit pressure* and should normally be in the vicinity of 10 to 15 cm in the gall bladder and 9 to 11 cm in the common duct (fig 5)

Figure 5 Transit pressure

The clamp is left on the tube leading from the perfusing bottle. After several minutes the fluid level in the manometer will stabilize at a point normally about 4 to 5 cm below the transit pressure of the cystic duct and 2 to 3 cm below that of the common duct. This represents the *residual pressure* (fig 6). These two pressures, the *transit* and *residual*, should be repeated two or three times and films taken at each pressure.

Figure 6 Residual pressure

Under normal conditions the transit pressure of the common duct must be lower than that of the cystic duct, otherwise emptying of the gallbladder would produce hypertension in the common duct. The pressures first described are the ones we have recorded during operations. Other investigators have made these studies preoperatively by transhepatovesicular puncture<sup>12</sup> or postoperatively through a cholecystostomy or T tube.

#### DISCUSSION

Biliary radiomanometrics has been used by its originators to study the sphincter systems of the gallbladder and the common duct in patients who have been subjected to intubations of these organs. Reactions to drugs and various stimuli have been determined by this technique. The physiologic individuality of the gallbladder sphincter as a neuromuscular apparatus of the gallbladder neck and cystic duct has been established.

Morphine has a more pronounced action on the gallbladder sphincter than on the common duct sphincter. It may throw the

At this point in the procedure, the tube leading from the perfusing syringe is opened and the apparatus is raised a few centimeters at a time to determine the pressure required to open the sphincter. The tube is clamped after every elevation. At a certain point the fluid level in the manometer will suddenly drop indicating that the dye has passed through the cystic duct, if the gall bladder is being studied, or through the sphincter of Oddi, if the common duct is being studied. This is called the *transit pressure* and should normally be in the vicinity of 10 to 15 cm in the gall bladder and 9 to 11 cm in the common duct (fig 5)

Figure 5 Transit pressure

The clamp is left on the tube leading from the perfusing bottle. After several minutes the fluid level in the manometer will stabilize at a point normally about 4 to 5 cm below the transit pressure of the cystic duct and 2 to 3 cm below that of the common duct. This represents the *residual pressure* (fig 6). These two pressures—the *transit* and *residual*, should be repeated two or three times and films taken at each pressure.

Figure 6 Residual pressure

Under normal conditions the transit pressure of the common duct must be lower than that of the cystic duct, otherwise emptying of the gallbladder would produce hypertension in the common duct. The pressures first described are the ones we have recorded during operations. Other investigators have made these studies preoperatively by transhepatovesicular puncture<sup>12</sup> or postoperatively through a cholecystostomy or T tube.

#### DISCUSSION

Biliary radiomanometrics has been used by its originators to study the sphincter systems of the gallbladder and the common duct in patients who have been subjected to intubations of these organs. Reactions to drugs and various stimuli have been determined by this technic. The physiologic individuality of the gallbladder sphincter as a neuromuscular apparatus of the gallbladder neck and cystic duct has been established.

Morphine has a more pronounced action on the gallbladder sphincter than on the common duct sphincter. It may throw the

whole gallbladder sphincter mechanism or isolated parts of it into spasm. It produces a tonic spasm of the wall of the second portion of the duodenum and the common duct sphincter. While morphine causes a contraction of the gallbladder sphincter, muscular area alone a fatty meal will throw the entire gallbladder and its sphincter apparatus into spasm.

Amyl nitrite suppresses functional spasm of muscle tissue in the gallbladder sphincter area. Through its action on the smooth muscle it relaxes the sphincter of the common duct and the entire duodenum in less than two minutes. Atropine produces a paralytic dilation of the wall of the second portion of the duodenum and releases the sphincter of the distal common duct. It has the same effect on the gallbladder sphincter. Atropine and amyl nitrite are very useful in differentiating organic from spasmodic stenosis in these areas.

By radiomanometric study of the Meltzer Lyon test, Caroll<sup>11</sup> concluded that the results depend on (1) an acceleration of the bile flow from the liver, (2) relaxation of the duodenal wall, the sphincter of Oddi, and of the gallbladder, and (3) slight to moderate contracture of the gallbladder. This test does not depend on the integrity of the sphincter of Oddi, inasmuch as the same train of events occurs if there has been a choledochoduodenostomy.

Debouvri<sup>12</sup> in his thesis stated that he had never observed a pharmacodynamic action of a drug on the common duct opening that was not the same on the wall of the duodenum.

Biliary radiomanometrics has achieved its greatest usefulness in elucidating the functional and organofunctional disorders of the biliary apparatus. Those syndromes although long suspected could not be accurately delineated by simple cholangiography. Chronic noncalculous cholecystitis is the general term used to include these disorders which have been variously called "cholecystatonia," "irritable gallbladder," "intolerant gallbladder," et cetera. By means of the radiomanometric test the French authors have been able to group the different functional diseases of the biliary tract into three entities: the hypotonias, the hypertonias, and the hyperesthesias.

By this technique it has been possible to show that "strawberry gallbladder" or "lipoidosis of the gallbladder" is an entity that starts as a chronic inflammatory lesion of the cystic duct which later gradually involves the neck and body of the gallbladder. The condition is shown by manometric evidence of partial obstruction and a climbing residual pressure.

#### ABNORMAL RADIOANOMETRIC FINDINGS

Obstruction of the cystic duct may be partial or total. It may be impossible to produce passage of dye through the cystic duct with

pressures up to 50 cm of 35 per cent Diodrast solution. If this is functional, it will be overcome in a few seconds with inhalation of amyl nitrite. If amyl nitrite has no effect, it is an indication of an organic lesion. Because this is not usually evident on inspection or palpation, we must rely on this test to indicate that a normal appearing gallbladder should be removed.

If transit through the cystic duct is accomplished, but only at an abnormally high pressure, and this is not relieved by inhalation of amyl nitrite, a partial organic obstruction may be assumed to exist. This is also an indication for cholecystectomy. The cystic duct, if studied microscopically, will demonstrate the presence of an organic lesion.

### CASE REPORTS

**Case 1** A 44 year old man with several years' history of alcoholism, upper abdominal pain, nausea and vomiting had a subtotal gastrectomy for postbulbar duodenal ulcer in November 1953. He was not helped by this operation. Serum amylase determinations made subsequent to this operation were elevated. On 1 April 1956 an exploratory operation was performed and a diagnosis of chronic recurrent pancreatitis made. The gallbladder was thin-walled and no abnormality was felt on palpation or inspection of the gallbladder or cystic duct. There were several large nodes about the common duct and a localized induration in the head of the pancreas. Manometric studies of the gallbladder with 35 per cent Diodrast solution repeated twice gave a transit pressure of 35 cm and a residual pressure of about 34 centimeters. There was almost imperceptible passage of dye through the cystic duct. Transit and residual pressures of the common duct were also elevated, and a transduodenal sphincterotomy was performed.

**Pathologic findings** Microscopic study (hematoxylin and eosin stain) of a biopsy specimen of the gallbladder wall showed markedly dilated Rokitsky Aschoff sinuses and minimal chronic inflammatory infiltrate (fig. 7). Cross section of the cystic duct showed thickening of the wall and chronic inflammatory reaction (fig. 8).

**Comment** Obstruction of the common duct may be complete or partial, as in the cystic duct, and the same tests with amyl nitrite will differentiate functional disturbances. Radiomanometric examination of this area will help reduce the 50 per cent postcholecystectomy disease seen after removal of the noncalculous gallbladder. It is much easier to overlook pathology in the common duct than in the gallbladder when relying only on inspection and palpation.

A raising of the transit pressure above normal may be the only clue to a disorder of the lower common duct if on repeated determinations of residual pressure it is found to be higher on each reading. The syndrome is recognized as the climbing of residual pressure of the common duct. This is usually seen

Figure 7 (case 1) Hematoxylin-eosin stained section of gallbladder wall showing markedly dilated Rokitsansky-Ascoboff sinuses and minimal chronic inflammatory infiltrate

(Figure 8 (case 1) Cross section of cystic duct showing thickening of the wall and chronic inflammatory reaction.

irregularities or inflammation of the sphincter of Oddi and the surrounding duodenum. Residual odditis is one of the most frequent and poorly understood causes of complications after cholecystectomy or choledochotomy for lithiasis. When slight hypertension of the sphincter of Oddi is confirmed, even in the face of normal appearing cholangiograms, the common duct should be decompressed by drainage or sphincterotomy.

**Case 2.** A 66 year-old woman had a cholecystectomy in January 1956 because of nonvisualization of the gallbladder and recurring epigastric pain. This was reported pathologically as normal. She was admitted in June with slight jaundice. An exploratory operation was performed on 31 July. No cystic duct stump remained. The common duct and pancreas were normal to palpation and inspection. Manometric readings of the common duct were slightly elevated. The initial transit pressure was 15 cm of 35 per cent Diodrast solution. The residual pressure was 13 centimeters. On repeated readings these rose to 20 and 18 respectively. Five cholangiograms, taken at various pressures, revealed only abnormal injection of the hepatic radicles. The common duct was not particularly enlarged and dye appeared in the duodenum. The duodenum was opened and a sclerotic, partly stenosed papilla was incised.

**Histologic findings.** Histologic examination of a biopsy specimen from the papilla showed a chronic inflammatory reaction with scarring involving the common bile duct and the immediate duodenal mucosa.

**Comment.** If the hepatic radicles or the duct of Wirsung are filled under a normal pressure of from 10 to 15 cm, some degree of obstruction at the papilla of Vater is suggested.

Cattell<sup>14</sup> stated that he and his associates surgically explored the common duct in 35 to 45 per cent of all gallbladder cases in order to avoid overlooked stones. Routine use of radiomanometric study of the common duct through the cystic duct should provide more exact indications for surgical attack on the common duct.

The value of this technic of preoperative common duct radio manometry over the methods of inspection, palpation, simple cholangiography, and surgical exploration of the common duct, available to surgeons today, is typified in the experience of Vallet-Guy.<sup>15</sup> In order to evaluate this procedure he surgically explored 100 common ducts containing stones. After the common duct had been opened, explored, and the stones removed, radiomanometric studies were made on these ducts. By this procedure 12 were found to still contain undetected stones or fragments. Two showed compression by pancreatitis. Five contained noncalculous obstruction. Twenty-two presented hypertonic reactions of the sphincter, some of which may have been the result of instrumentation. Causes for fistula and postoperative recurrence were thereby reduced.

Surgeons who have done cholangiograms at the time of operation have been dissatisfied with them, because they have not been reliable in disclosing stones. If multiple exposures are made at various pressures, stones are much less likely to be overlooked.

We have found this study useful when done postoperatively through an indwelling T tube. The finding of normal intracavitary pressures and free flow of dye into the duodenum with relatively normal resistance and without evidence of calculi or other obstruction gives one practical assurance that removal of the T tube will not be followed by fistula or cholangitis. The following two cases are illustrative.

**Case 3.** A 59-year old man was admitted on 13 August 1956 with acute cholecystitis of two days' duration. He had had no previous symptoms of gallbladder disease. The acute symptoms subsided rapidly on conservative therapy. He was given clearance by the medical service on the basis of his hypertensive cardiovascular disease secondary to generalized arteriosclerosis. Three efforts at oral and intravenous cholecystography were unsuccessful. Serum bilirubin was 1.8 mg per 100 ml, all of which was direct. An exploratory operation was performed on 31 August and a subacutely inflamed abscessed gallbladder containing many calculi was removed. The common duct was dilated and explored. No stones were found. A Bakes dilator No. 9 was passed through the sphincter into the duodenum without difficulty. A T tube was inserted. On 5 September the T tube was clamped but had to be released because of copious drainage around the tube. On 12 September the patient was taken to the fluoroscopic room where his common duct was studied by radiomanometric technique. Intracavitary pressure was found to be 9 cm of 35 per cent Diodrast. Transit pressure was 15 cm and at this point dye flowed freely into the duodenum. Residual pressure was consistently 11 cm. Cholangiograms made at this time were negative for calculi. The T tube was clamped for four days without incident and then removed. No further bile leakage occurred. The wound healed promptly and the patient was discharged shortly in an asymptomatic condition.

**Case 4.** A 78 year old man was admitted 17 October 1956 with acute cholecystitis of one day's duration. He had had no previous symptoms of gallbladder disease. He had had several transurethral resections for carcinoma of the prostate and had been on estrogen therapy for several years. Within two days after admission he became clinically jaundiced and his condition deteriorated making exploration mandatory. A cholecystostomy was performed and four ounces of calculi were removed from the acutely inflamed gallbladder. Without manometric control dye was injected into the common duct through the cystic duct. No dye entered the duodenum and there was suggestive evidence of common duct calculi. The common duct was opened and two calculi recovered. A T tube was inserted and again a cholangiogram was done with moderate but unmeasured pressure through a syringe. The common duct was apparently normal but no dye passed into the duodenum. Because of his precarious condition at this time further surgery was not attempted and

he was returned to his room with a cholecystostomy tube and a common duct T-tube in place. His jaundice cleared and recovery was uneven but Eleven days after the operation he was taken to the fluoroscopic room and studied by radiomnometric technique. The intracavitary pressure was found to be 5 cm of 35 per cent Diodrast. At 15 cm of pressure the common duct outlined well and dye flowed freely into the duodenum. Residual pressure was consistently between 10 and 11 cm. The biliary tree was clear of calculi. Both tubes were clamped off for six days and then removed. There was no further drainage and cholangitis did not develop. The patient was discharged within a few days without complaint.

Even though the transit and residual pressures were slightly elevated in these two patients, the evidence of free flow through the distal common duct and the several cholangiograms made during the study assure us that the tubes could be removed safely. It is likely that the severity of the acute inflammation and the trauma incident to the surgery explains these slightly elevated readings.

It seems that this technique represents an aid to the surgeon by reassuring him during the operation. It also assures the patient accurate and curative treatment at the proper time.

#### SUMMARY

The many unsatisfactory results following surgery of the biliary tract indicate that the presently used diagnostic methods are inadequate. The technique of radiomnometrics in which pressure readings and contrast roentgen studies are made simultaneously at the time of surgical intervention has been described. The apparatus, the method, and some of the normal and abnormal findings have been outlined. This technique represents a refinement of simple cholangiography and if routinely used, the incidence of postoperative biliary sequelae should be reduced. It is of great value in elucidating organic, functional, and mixed syndromes of the biliary tree.

### CONFIDENCE

Confidence is an infectious thing—the doctor who possesses it is the doctor who can give it to others. It must be sincere. It is not much use pretending you are sure when you are not—the patient can tell. Confidence is invaluable because if you are certain you are right and if you can convince the patient that you are right then whether you really are right or not often makes very little difference. Yet the doctor should not assume omniscience. I have a notion that doctors do not often enough say "I do not know." It is better to tell a man confidently that you don't know than to tell him unconvincingly that you do. Patients can appreciate sincerity and truthfulness more than some people realize.

# TREATMENT OF ANTICHOLINESTERASE POISONING BY PHOSPHATE INSECTICIDES AND "NERVE GAS"

STEPHEN KROP Ph D  
TED A LOOMIS Captain, MC USAR

THE advent of potent anticholinesterase compounds as insecticides and the possibility that some member of this broad group of chemicals might be used in war as "nerve gas" present the medical practitioner with an urgent treatment problem in cases of severe poisoning which he otherwise sees only in such emergencies as severe cyanide or carbon monoxide, or aconite poisoning, severance of the carotid artery or acute bilateral pneumothorax. Some of these compounds such as diisopropyl phosphorofluoridate (DFP), triethyl phosphorite (TEPP), paranitrophenyl diethyl thionophosphate, etc., have a degree of toxicity exceeded by few other chemicals. They may cause death in a very few minutes after contact, ingestion, or inhalation of a very small amount. They occur so rapidly, primary reliance for treatment must be placed on the general medical principles which apply. These agents are used as insecticides or in a limited number of civilian populations. Therefore, it may be useful to review the known major actions of these compounds in order to assist the physician with the principles of treatment.

These compounds are, in the main, liquids of high boiling point, having little or no odor, exerting no irritation on the skin, eye, or respiratory tract in liquid or vapor form, thus providing no simple warning of exposure. Hence, their great toxicity and insidiousness render them highly dangerous.

## MODE OF ACTION

The only clearly defined biochemical lesion resulting from the action of these compounds is the long lasting inactivation of cholinesterases<sup>1-3, 7-11</sup> which normally destroy acetylcholine

The body "neurohormone" acetylcholine is believed to be intimately associated with impulse formation and propagation in nervous tissue and at the neuromuscular junction, with smooth muscle activity, with secretory activity of many glands and with the regulation of the cardiovascular system. For convenience in understanding the aims of treatment the effects of these poisons may therefore be regarded as those of acetylcholine: i.e. stimulation of the cholinergic portions of the autonomic nervous system and stimulation and paralysis of the central nervous system and of the neuromuscular apparatus. Acetylcholine effects have also been termed "muscarinic" and "nicotinic" (Other actions of anticholinesterase compounds have been reported but they probably are not significant from the standpoint of therapy.) From these considerations the actions of these compounds may be deduced or explained.

### SYMPTOMATOLOGY

There are considerable variations in relative prominence of groups of symptoms, in time of onset and greatest severity of symptoms and in time to death as illustrated by the rapid acting sarin and TEPP on the one hand and the slow acting parathion, on the other. However in each case it is possible to regard the symptoms as arising from a common cause and to consider the problem of treatment as fundamentally the same for all members of this class of poisons.

On the basis mainly of observations in animals the following symptoms can be expected to appear in rapid succession after severe exposure to sarin or TEPP: rhinorrhea, salivation and miosis, difficulty in breathing followed by cyanosis, collapse, and convulsions, sweating, urination and defecation, paralysis of respiration with extreme cyanosis. The pulse may be slow or absent and blood pressure low after an initial elevation. Heart block, partial or complete, may accompany the low heart rate which may persist until death. Widespread or localized twitching of skeletal musculature and subsequent persistent weakness appear. A severe case of anticholinesterase poisoning will present itself as one of acute asphyxia. On the other hand these symptoms appear and develop more slowly in parathion poisoning.

It is obvious that not all of the symptoms enumerated must be controlled to ensure survival. For example, sweating and miosis will not cause death but interference with respiration at any point between nostril or mouth and the tissues may be lethal. Hence this action of the anticholinesterases is the central problem in the treatment of the severely poisoned. The symptoms of primary lifesaving importance are those arising from the action of these compounds on organ systems whose failure results in

asphyxia The means by which body tissues are assured of an adequate oxygen supply may be regarded as follows

1 Those concerned with ventilating the pulmonary alveoli The anticholinesterases act to increase the resistance of the lung to inflation (bronchoconstriction),<sup>17-20</sup> obstruct the upper airway by secretions,<sup>1,24</sup> interfere with the operation of the respiratory center by convulsions<sup>21,22</sup> and by paralysis,<sup>21,22</sup> and interpose neuromuscular block to the muscles of respiration<sup>23</sup>

2 Those concerned with delivering oxygenated blood from the lungs to the tissues In anticholinesterase poisoning propulsion of blood to the tissues is hindered or lost by the slowing or arrest of the heart<sup>23,24,25</sup> and by increased resistance in the pulmonary circuit<sup>23</sup> Such action may explain acute collapse

Therefore, the therapeutic challenge is to combat the effects of anoxia Effective respiration must be maintained, and cardiovascular support must be provided

### TREATMENT

Further absorption of the poison obviously must be prevented by removal of the casualty from the poisoned atmosphere, masking, washing the skin and eye, or gastric lavage—whichever is indicated by circumstances of the exposure Oropharyngeal secretions must also be cleared However, in view of the rapidity with which symptoms may become serious, as already indicated, treatment must be instituted without delay

Drug treatment of anticholinesterase poisoning may logically be approached by (1) chemical destruction or inactivation of the poison already in the body, (2) reactivation of the cholinesterase and destruction of the poison, and/or (3) blocking the effects of acetylcholine Important progress has been made in the direction of (1) and (2) by study of the action of certain hydroxamic acids in vitro and in vivo<sup>24, 26, 27</sup> However, the important element of time is yet to be satisfactorily overcome in these approaches since the hydroxamic acids act too slowly for practical usefulness and, for destruction or inactivation of the poison, must be given prophylactically to be effective \* Blocking the actions of acetylcholine with atropine, however, meets the time requirement for successful treatment, for its action is almost instantaneous after absorption and is of suitable duration Except for the neuromuscular action of acetylcholine, the actions of the anticholin

---

Similar compounds such as 2 pyridine aldoxime methiodide (PAM) reported after this paper was submitted for publication suffer from the same fundamental limitation In fact recent observations by one of us (T A L. to be published) indicate that PAM is ineffective as an antidote in experimental sarin poisoning Therefore no change in the conclusion of the present paper that atropine is the backbone of drug therapy of severe anticholinesterase poisoning is indicated at this time

esterases having life or death importance are controllable to an important extent by atropine by its known anticholinergic action in the central nervous system smooth muscle glands and circulation<sup>24 25</sup> Similarly atropine readily prevents or reverses the actions of the anticholinesterases<sup>17-23 27 28</sup> and by itself exerts considerable lifesaving action if given early enough and in sufficient dosage in cases of severe poisoning<sup>2 6 27 28</sup>

Artificial respiration will be necessary in all cases where respiratory embarrassment or failure exists. Positive pressure ventilation will be needed if the airway resistance is increased. Although atropine in feasible dosage does not effect the neuromuscular block exerted by the anticholinesterase compounds it makes possible the successful application of artificial respiration by erasing the lung impedance to ventilation by controlling airway secretions, by relieving the cardiovascular effects, and by controlling convulsions<sup>19 20 22</sup> It also hastens recovery of the respiratory center<sup>21 22</sup> and spinal reflexes<sup>16</sup> It should be noted that convulsions will impede artificial respiration and may prevent intravenous therapy

The toxicity of atropine is low,<sup>29 30</sup> considering its high anticholinergic potency, and in severe anticholinesterase poisoning the dosage of atropine may need to be quite high by comparison with doses used for other purposes<sup>1-6 11</sup> In the past treatment failures in severe insecticide poisonings have been due to too little atropine given too late. In general it must be given repeatedly in doses sufficient to control the effects on respiration and circulation or sufficient to maintain a mild degree of overdosage (dryness of the mouth and skin). The initial dose should be 2 mg of atropine sulfate or tartrate intramuscularly, repeated as the clinical condition indicates. The chief drawback to atropine is its interference with sweating, an important avenue of heat loss from the body in warm climates this must be carefully observed<sup>11 12 14</sup> Other drugs possessing the desirable properties of atropine to an improved extent and with greater lifesaving potency are being sought and some have shown promise<sup>1-6 14</sup> but their possibilities all factors considered are yet to be established. In the meantime, reliance on atropine for drug therapy of anticholinesterase poisoning must continue.

# PERSONAL IDENTIFICATION BY MEANS OF THE TEETH

ROBERT D WYCKOFF *Captain DC USN*

**T**HE determination of personal identity is the recognition of an individual by characteristics which distinguish that one person from all others.<sup>1</sup> Fingerprints are considered the best means of identification because they have characteristics in great variety, have individuality, do not change throughout life, and can be accurately recorded.

Although the teeth have individuality and possess a great variety of characteristics that can be accurately recorded, the dental record must be kept up to date if it is to be accurate throughout life because of changes in the dentition caused by extractions, dental prosthesis, operative dentistry, or accidents. For this reason, and because cases in which fingerprints are not available are relatively few, the teeth have not received popular acclaim as a means of identification. If complete and currently accurate dental records are available, the teeth provide an excellent and in some cases, the only means of identification. Without an accurate record for comparison, however, the teeth alone become merely clues which may assist in identification only by giving evidence of age and race.

Teeth have been used as a means of establishing identity for several hundred years,<sup>2</sup> but this method is not likely to be used to any great extent in the civilian population unless dental records are made on the entire population and changes that have occurred in the dentition recorded at least once every two years. Ideally, there would be a coding system and the records would be kept on file in a central agency, such as the Federal Bureau of Investigation. The feasibility of such a system is questionable when the number of probable cases is compared with the cost. Although civilian dentists keep accurate records in many instances, they record only the treatments rendered. This, along with the shifting nature of our population, usually results in the non-

---

<sup>2</sup> From Dental Division, Bureau of Medicine and Surgery, Department of the Navy, Washington, D.C.

availability of complete records for use by the civilian investigator

### FACTORS ENABLING IDENTIFICATION

There are two principal factors which make the teeth unique as an aid to determining personal identity.<sup>3</sup> The first is the indestructibility of the crowns of the teeth, their supporting bony structures, and the restorative materials that are used by the dental profession. In cases of extreme mutilation by fire, force, or submersion, the teeth often provide the only evidence upon which identification can be made. The enamel of the crowns is approximately 95 per cent mineral, is almost completely resistant to deterioration by air, earth, or water, and is damaged or destroyed only by extremely high heat, exceptionally great mechanical forces, or chemical agents. The materials used in restorative dentistry are even more resistant. Commonly used gold alloys melt in the range of 1,600° to 2,000°f. The porcelain of bridges and artificial dentures is resistant to temperatures up to 2,000°f and the nonprecious metals that are used in the fabrication of partial dentures have even a higher melting point. Without this quality of resistance of the enamel and restorative materials to fire, the identification of many air crash victims would be impossible.

The second factor which makes the teeth a unique means of identification is the extreme improbability of there ever being two persons with identical sets of teeth. Even in the "perfect" dentition, shape and size of the arch and mold and shade of the teeth, as well as spacing and anatomical imperfections, make identical sets unlikely. On the Navy Dental Record there is a space for remarks that is used to record identifying characteristics other than missing teeth, caries, and restorations. Dental officers are instructed to give special attention to recording the identifying characteristics of the perfect dentition. In most cases, however, the dentitions have missing teeth, caries, and restorations in various combinations, none of which are alike.

### RELIABILITY

The unlikelihood of identical dentitions is evident from the number of combinations which are possible with 32 teeth. From the formula  $2^n - 1$  it is found that possible combinations number over four billion. If the five surfaces of each tooth and the possibility of different types of restorations were calculated, the astronomical figure resulting would make it obvious that there is almost no chance of two dentitions being alike and that if the chart of an unknown matches that of a known, even though not completely, there is no doubt that the charts were made from the same dentition (fig. 1).

Identification of an unknown by means of a dental record could be compared to a prediction that he has certain dental characteristics. It is doubtful that one could predict without previous knowledge of his dentition that a certain individual had, for example, a mesio occlusal amalgam in the lower right second molar in combination with a distal silicate on an upper lateral incisor and a mesio occlusal amalgam on the upper left second bicuspid. These are three frequently occurring artificial character

Figure 1 In October 1956 a naval officer was killed when his car went over a 400 foot cliff by the ocean. The car was buried by a landslide and when it was found after 10 days there was no body in the vicinity. Thirty days later an unidentified body washed up on the beach eight miles from the site of the accident. The chart above (left) was made from the dentition of the body. It was determined by the Navy dental record (right) that the body was that of the missing naval officer. Inasmuch as the officer had access to vital top secret information his disappearance had caused concern and a great desire to learn his true fate. (The markings on the dental charts are restorations. X indicates missing teeth.)

istics, but to guess three out of three would be highly improbable because the number of tooth surface combinations in a complete dentition is equal to  $1435 \times 10^{47}$ . Therefore if the prediction is made from a dental record that these characteristics should exist and it is subsequently found that they do the individual is positively identified.

The value of the teeth for determining the personal identity of casualties caused by fire, drowning and battle has been proved many times in the armed services. Even in peacetime the hazards of sea and air present a frequent requirement for identification by means of the dental record. This is made easier in the case of military personnel by supporting evidence such as (1) authoritative knowledge of the geographic location of all personnel (2) daily muster of personnel making it virtually impossible for the absence of a person to go unnoticed and (3) information usually available that the casualty to be identified may be a certain person or one of a certain group.

## METHOD

Upon entry into the Navy or Marine Corps each person receives a dental examination, and all missing teeth, existing restorations, dental caries, and abnormalities are recorded in duplicate on Standard Form 603—Dental Record. The original record accompanies the individual throughout his career and each dental treatment is entered on his record as it occurs. The duplicate record is sent to the Bureau of Medicine and Surgery in Washington, D C, where it remains until the member is separated from the service. At that time the original and duplicate records are sent to the Naval Records Management Center, St. Louis, Mo., for permanent filing. The number of records on file in St. Louis is over nine million, and from this source assistance has been rendered to civilian authorities in identifying the unrecognizable remains of persons known to have served in the Navy or Marine Corps (figs 2 and 3). The permanency of these records is protected—an Act of Congress would be required to have them destroyed.

When the personal identity of Navy or Marine Corps personnel must be determined by means of the teeth, requests for assistance are directed to the Dental Division of the Bureau of Medicine and Surgery. Assistance may be given in several ways, depending upon the requirements of the situation. If the original dental record is not available at the activity or aboard the ship to which the deceased was attached, a record may be made from his teeth and transmitted to the Bureau for comparison with the duplicate record, or else the recordings of the duplicate dental record may be transmitted from the Bureau to the activity or ship. Dental records within the United States can best be transmitted by telephone. When a record is required at an overseas base or aboard a ship it is sent by dispatch, however, where multiple records are required the dispatch becomes so long and cumbersome that errors in transmission may result. Mailing of dental records is seldom satisfactory because identification usually is urgent, to make possible the notification of next of kin and preparation of remains for shipment and burial.

Problems in determination of personal identity have been of the following types:

1. Identification in absence of any supporting evidence
2. Identification aided by supporting evidence that the remains may be those of a certain individual or of one of a known group
3. Identification of each unknown in a known group
4. Verification of identification already made by other means

When the dental record of a known is compared with that of an unknown, it is not mandatory that the two records

in order to establish positive identification. It is mandatory, however, that there be unquestionable points of similarity between the two records with no existing impossibilities, such as restorations on the dental record of the known which do not exist on the record made from the teeth of the unknown casualty. Points

Figure 2. A mandible was found on a California beach in 1954. Police investigation revealed that it could possibly have been that of a man who had drowned in that area a year before. His body had never been found. He had served in the Navy in World War II. A positive identification was made by comparing the mandible with the Navy dental record (right). The chart (left) was made from the mandible. The empty root sockets in the mandible indicated that all teeth had been present at the time of death.

of similarity may be defined as artificial or natural dental characteristics that appear to have been recorded from the same individual.

No set percentage or set number of points of similarity should be required for establishing a positive identification, both because the number of natural and artificial dental characteristics varies and because each characteristic has a relative value based on the average rate of occurrence. Characteristics that rarely occur have greater value in establishing identity than those which occur frequently. By considering frequency of occurrence, the

Figure 3 The chart above (left) was made in 1950 from the dentition of a skeleton found in the Mojave Desert. It was not until five years later that a billfold found in the area indicated that the skeleton might have been that of a Marine officer who had been missing since 1947. The dental record (right) made in 1946 when the Marine officer was discharged was obtained from the Naval Records Management Center and positive identification was made as a result of the comparison.

investigator may be able to establish positive identification, if no impossibilities exist, from a few or perhaps just one rarely occurring characteristic, whereas he would require the combination of several frequently occurring characteristics. For example Gold restorations provide better evidence than amalgam, missing cuspids than missing first molars, and lingual surface caries than occlusal surface caries.

The final determination as to whether the dental record of the known is also that of the unknown rests on the judgment of the investigator after evaluating the dental evidence at hand. In the Navy and Marine Corps where reasonably accurate records are available, experience has shown that when the record of the known is compared with that made from the unknown there is seldom any doubt. In almost all cases the record either matches or does not match.

## DISCUSSION

The importance of identification of the dead cannot be over emphasized. Establishment of personal identity is not only a passive sort of comfort to the next of kin but often is a requirement in the settlement of legal entanglements. Because cases that require identification by means of the teeth are relatively few, there is no organized body of dental experts in this field, nor are there any persons who spend full time in the science of forensic dentistry. It is however within the capability of all dentists to assist in the identification of the dead when teeth are involved. The determination of personal identity by means of the teeth therefore is a service to the other forensic sciences that may be rendered by the dental profession.

## SUMMARY

Complete and accurate dental records provide an excellent and sometimes the sole means of identifying the remains of active-duty military personnel and of civilians who have had previous military service.

Two factors make it possible to use the teeth for this purpose. (1) The crowns of the teeth, their supporting bony structures, and the restorative materials used by the dental profession are almost indestructible, and (2) there is little chance of there ever being two persons with identical sets of teeth.

# ENURESIS AND SPINA BIFIDA OCCULTA

SHELTON P. SANFORD *Captain MC USN*  
GILBERT W. KLIMAN, *Lieutenant MC USNR*

**T**OILET training and toilet habits are a source of varied pleasure and pain. Psychoanalytic studies reveal that much of our aggression, guilt, shame, and disgust, as well as happiness, are firmly associated with our toilet experiences. In such an area, one must expect that medical judgment will be difficult. Any objective contribution to our understanding of toilet habits will be especially valuable, since objectivity will be difficult to obtain except through unusual self knowledge or carefully designed experiment. The following article is a mundane matter of the latter sort: a study of the frequency with which an occult vertebral defect appears among enuretic patients and controls.

A satisfactory working definition of "enuresis" is "frequent urinary incontinence past the age of five, occurring primarily at night." Some definitions require the patient only to wet his bed past his third birthday, and still other definitions include daytime incontinence. Some authors require a frequency minimum of one episode of urinary incontinence per week. For practical purposes, such differences in definition are of little consequence in the area where enuresis is most frequently a large scale problem: military recruit selection. Our experience with enuresis was gained while observing patients in recruit status at this training center. Here, 0.3 per cent of all incoming recruits are discharged each year with the diagnosis "Immaturity reaction with symptomatic habit formation: enuresis." The occurrence of bedwetting even once or twice a month is enough to cause serious personal handicap to a recruit in the compulsively cleanliness conscious environment of a barrack or crew's quarters. As the diagnosis implies, an enuretic recruit is considered to suffer a personality disorder of which enuresis is only one symptom.

Studies of enuresis have been in two directions. Students of physiologic and anatomic orientation have sought electroencephalographic abnormalities,<sup>1</sup> urethral valve disorders, cystitis, and spina bifida occulta as causes. Students of personality disorder

have generally expanded on Freud's concept that enuresis is a masturbation equivalent. Among the enuretic patients of military age little support has been found for the etiologic importance of anatomic defects. Much work has however supported the psychologic viewpoint<sup>2</sup>—both by eliciting evidence of personality disorder among these patients and by either curing or decreasing the severity of the condition with psychotherapy.

The present study was undertaken in a spirit of wishing to do some justice to the anatomic approach at a time when personality studies have been greatly emphasized. One of us had long suspected that spina bifida occulta might frequently cause enuresis. This suspicion was a natural one. Enuresis is certainly a prominent difficulty for patients with manifest spina bifida particularly where other neurologic defects appear. Ingraham and Lowrey<sup>3</sup> reported that 7 of 65 children with spina bifida occulta were seen initially with complaints of "enuresis or other form of incontinence." Their surgical exploration of patients with spina bifida occulta and associated symptoms often disclosed a definite occult meningocele or a fibrous tract attached to the meninges or a lipoma within the gaping vertebral canal. Such associated abnormalities provide a mechanical explanation for neurologic symptoms that were seen in the patients studied.

Symptom producing abnormalities may lurk beneath an apparently innocuous and occult vertebral defect. Craig and Mulder reported the case of a 12 year old girl in whom severe neurologic symptoms were produced by a large fat pad which compressed the dura beneath a maldeveloped fourth lumbar spinous process. In addition the filum terminale was attached to the dura opposite the fourth lumbar vertebra exerting traction on the conus medullaris. Jelsma and Ploetner<sup>4</sup> found 48 out of a group of approximately 6 000 cases of low back pain in which they thought the pain was produced by spina bifida occulta. Such cases suggest that a disproportionate growth of the vertebral column might exert traction on the lower spinal cord by means of a fibrous tract between the cord and a vertebral defect. They provoke serious consideration of how often such abnormalities might occur in routinely observed and even asymptomatic cases of spina bifida occulta.

Evidence for relationship between occult spinal bifida and enuresis is uncertain. A pioneering study of military recruits was made prior to World War I by Fuchs<sup>5</sup> who reported a syndrome (*Myelodysplasia*) consisting of enuresis, lumbosacral superficial anomaly and roentgenographic evidence of spina bifida occulta. It was not until 1927 that a scientifically satisfactory study of enuresis and spina bifida occulta was made. This work by West,<sup>6</sup>

detracted much from previous anatomic and roentgenographic studies. He found no statistical relationship at all! Principal difficulties in reports on this subject are lack of properly selected control cases and lack of stated criteria for identifying spina bifida occulta on roentgenograms. These difficulties seem adequate to account for lack of agreement as to the incidence of spina bifida occulta among the general population and among enuretic patients. An example of a recent work which is difficult to evaluate, because it lacks controls, is Terulano and Jannelli's<sup>8</sup> study of 15 enuretic patients with spina bifida occulta. From their study, one can make no estimate of the frequency with which the spinal defect occurs in a comparable group of the nonenuretic population, and no estimate of the frequency of the defect among the general population of enuretic patients. The range of disagreement in the literature is well illustrated in table 1.

TABLE 1 *Spina bifida occulta*

Subjects studied by	Number of cases	Lumbar or sacral defect (per cent)	Lumbar defect (per cent)	Sacral defect (per cent)
Southworth & Bersack <sup>3</sup>	550	18.2	2.2	16.0
Hadley <sup>10</sup>	1,500	5.2	0.2	5.0
Brailsford <sup>11</sup>	3,000	17.0	6.0	11.0
Sutherland <sup>12</sup>	12,000	5.0	1.5	3.5
Wheeler <sup>12</sup>	1,000	36.0	23.0	13.0
West <sup>7</sup>	100	48.0		
Enuretics studied by				
West	81	51.6		
Mertz <sup>14</sup>	32	68.0		
Karlin <sup>15</sup>	25	84.0		

Of the studies listed in table 1, the best is the previously mentioned 1927 study of British recruits by West. West used 100 randomly selected controls and 100 enuretic patients, and also graded spina bifida occulta according to five degrees of severity. He found no difference in the incidence of spina bifida occulta among the two groups. In addition, he found that actually had a greater incidence of the three most severe degrees of spina bifida occulta! Working from a different

Simon and Mills<sup>14</sup> also cast doubt on the relevance of spina bifida occulta to enuresis. They sought histories of enuresis among 53 children with proven spina bifida occulta in whom there was not only roentgenographic evidence of spina bifida occulta but also one or more of the following "Sensory changes in the saddle area and lower extremities motor changes in the perineum and lower extremities clubfoot or other associated congenital anomalies." None of the patients with spina bifida occulta as defined above was found to be enuretic.

### METHOD

Roentgenograms were taken of 196 consecutive enuretic patients seen in the neuropsychiatric unit of this training center. All patients were recruits in the first weeks of recruit training. Their complaint of current enuresis was generally substantiated by observations from their company commander and by the neuropsychiatric unit corpsmen as well as by past history. By arbitrarily selecting every seventh recruit arriving at the "receiving unit," 181 controls were obtained. No attempt was made to establish how many of the presumably normal controls were actually enuretic. A separate study however revealed that only one of 172 incoming recruits was currently enuretic. All roentgenograms were "routine" anteroposterior lumbosacral views which usually included the lower thoracic, all lumbar, and at least the first two sacral vertebrae. Because of this limitation no reference will be made to spina bifida occulta below the second sacral vertebra. A reading of "spina bifida occulta" was made whenever a complete lack of dorsal or ventral fusion of a vertebral arch was noted. Simple absence of a spinous process was not called spina bifida. Partial fusion defects were not included. Any complete nonfusion was considered a spina bifida no matter how small the distance between the unfused portions. Interpretation of each film was made separately by three physicians each unaware of the interpretations of the others. Films were read in such fashion that the interpreter was generally unaware of the identity of the case—whether enuretic or control. Despite the separation and "blindness" deliberately inherent in the study there was disagreement concerning only two of the 277 roentgenograms studied.

### RESULTS

An outline of our results is present in table 2. In the control group 57 cases of spina bifida occulta were discovered on the anteroposterior lumbosacral roentgenograms. Among the enuretic subjects 60 cases were discovered. No significant difference was found in the distribution, extent, or frequency of spina bifida occulta in the two groups. If any differences were suggested by

the data, such differences were in the direction of greater spinal abnormalities in the "normal" control group. That is, there were two thoracic defects among the controls and each involved three vertebrae. No thoracic defects at all were found among the enuretic subjects. In addition, there was a somewhat higher incidence of lumbar defects among the controls than among the enuretic subjects. There can be no doubt that the overall incidence of spina bifida occulta in the two groups studied is statistically identical. Furthermore, there is no statistical difference in the distribution of defects among the two groups. The small preponderance of thoracic and lumbar defects among controls is attributable to random variations. The findings of Karlin<sup>12</sup> and Mertz<sup>14</sup> have thus not been substantiated by our study of the relationship between enuresis and spina bifida occulta.

TABLE 2 *Spina bifida occulta among enuretic naval recruits (controls 181 cases enuretics 196 cases)*

Defect	Controls (per cent)	Enuretics (per cent)
Spina bifida occulta	31	31
Thoracic	1	0
Lumbar	2	1
Sacral (S1 or S2)	30	30

One case with a thoracic defect also had a lumbar defect. Another case with a thoracic defect had a sacral defect and a lumbar defect. One case had combined lumbar and sacral defects (L5-S1) without a thoracic defect. There is an overlapping of percentages because of combined defects.

#### DISCUSSION AND CONCLUSIONS

We have been unable to support a hypothesis that enuresis has a strong association with spina bifida occulta. A lack of statistical correlation does not exclude another possibility. It may still be that some enuretics with spina bifida occulta would reveal spinal cord lesions if surgically explored. Such was the experience of Ingraham and Lowrey when operating on a group of patients with various neurologic difficulties occurring in association with spina bifida occulta. On the other hand, our results tend to dismiss rather than raise hope for discovering the cord as a frequent cause for enuresis among the studied. We conclude that other causes will be studied.

# MODIFIED MARSUPIALIZATION OPERATION FOR PILONIDAL SINUS

An Ambulatory Treatment Using Lidocaine  
as a Local Anesthesia

DANIEL J ABRAMSON M D

**P**ILONIDAL cysts and sinuses in early adult life produce symptoms of irritation, soreness, persistent discharge, or abscess formation. Pilonidal disease presents a great problem to the armed services, and a tremendous number of man days are lost because of this condition. Casberg<sup>1</sup> found that about 80,000 such patients were admitted to Army hospitals during the years 1941 through 1945, with an average hospital stay of 55 days for those surgically treated by excision procedures.

The marsupialization operation, or exteriorization of the sac wall for treatment of pilonidal sinuses, was described by Buio<sup>2</sup> in 1937. In 1950, I developed an exteriorization procedure in which the lateral walls of the sinus were excised and the remaining sac was marsupialized. The merits of this technique have recently been discussed by Phelan.<sup>3</sup> Seventy-three unselected patients treated by this technique have been reported previously.<sup>4</sup> In the present study of an additional 109 patients, 32 were treated by the same method.

Since the exteriorized sac wall is quickly obliterated by healthy granulations, several adjunctive procedures were tried in an effort to shorten the healing time. These consisted of secondary closure with wire in 11 patients, and pinch grafting in three. The results, however, were not superior to the procedure finally adopted in the last 63 patients, in which all the sac wall was excised except for a small midline strip measuring one fourth inch or less in width. All of these procedures were performed in the outpatient surgical department of this hospital. Local field block anesthesia was used, and operations were performed as an in and out procedure.

Following operation, the patients are placed on quarters for from three to five days and on limited duty for three weeks, and

---

From Walter Reed Army Hospital, Washington 12, D. C. Dr. Abramson is also on the Surgical Staff of Georgetown University Hospital, Washington, D. C.

then returned to full duty. Since hospitalization is not required and patients are returned to duty quickly, there has been an attendant monetary benefit to the Army and a minimal loss of man days by the use of this technic. The simplified marsupialization operation is applicable to all types of pilonidal sinus. The healing time is short, the morbidity minimal, and the results excellent.

### TECHNIC

An oral antihistaminic is given prior to operation and the patient is placed on the operating table in a modified jackknife position. The buttocks and sacral region are shaved and separated by adhesive traction. The area is prepared for operation with suitable antiseptics. Anesthesia is accomplished by peripheral field block using a 1 per cent solution of lidocaine hydrochloride with epinephrine. The deeper tissues are infiltrated with the anesthetic agent—it is unnecessary to inject the skin. Anesthesia is rapid, long lasting, and extremely effective because of the diffusion properties of lidocaine hydrochloride.

A grooved director or mosquito clamp is inserted into the sinus opening and the skin overlying the instrument is incised (fig. 1). It is important to open superiorly and inferiorly into normal tissue. All hair and infected granulation tissue is removed by wiping with a gauze pad. The wound is then probed for addi-

Figure 1 The sinus tract is opened over a mosquito forceps (or grooved director).

April 1957)

tional openings, and any accessory tracts are removed to their extent.

The skin adjacent to the sac is circumcised in order to outline the amount of the sac wall to be removed. An incision is made in the skin and forceps are applied to the circumcised skin edge. By sharp dissection (fig 2) the sac wall is exposed. Underlying fascia is exposed. A careful search is made for additional openings.

Figure 2. The surrounding skin edge has been undercut. Allis forceps are on skin. An incision has been made and excised by sharp dissection. Follow on the opposite side—approximately one fourth inch of sac.

The skin edge is sutured to interrupted chromic No. 00 catgut sutures, a bite being taken in the deeper tissues. The sutures are later removed. The procedure is repeated on the opposite side, and when the operation is completed approximately one-fourth inch of sac remains (fig 3). If well defined, the entire area is covered by underlying tissues or presacral pressure dressing is applied. Given Aspirin with codeine.

edge of the remaining sac with interrupted chromic, a bite being taken in the deeper tissues. The procedure is repeated on the opposite side, and when the operation is completed approximately one-fourth inch of sac remains (fig 3). If well defined, the entire area is covered by underlying tissues or presacral pressure dressing is applied. Given Aspirin with codeine.

patient is then placed on quarters for from three to five days and after three weeks of limited duty he is returned to full duty.

The postoperative care is simple but is as important as the operative procedure itself. It is essential to stress that healing must occur from the base and that each patient must be followed until healing is complete. The patient returns on the second day for redressing and usually volunteers the information that pain was negligible. The sutures are removed on the seventh day and Sitz baths or hot compresses are begun. He is seen and redressed

Figure 3 The skin edge is sutured to the remaining sac wall with interrupted chromic catgut

about every five to seven days thereafter. The intervening dressings are done by the patient. At each dressing the wound is cleansed and rubbed gently with cotton applicator sticks. It is important to keep the surrounding area shaved in order to prevent growth of hair into the wound. The sac wall is soon covered with healthy granulation tissues. Exuberant granulations are cauterized with silver nitrate. Complete healing occurs in about three weeks.

#### COMMENT

A history of prolonged periods of drainage abscesses, or recurrences was characteristic of the majority of the cases. In this present series of 109 cases there were 14 acute abscesses that required incision and drainage prior to marsupialization. In a total

of 39 patients the following surgical procedures had been carried out earlier: incision and drainage in 26, excision and primary closure in 6, and excision and open packing in 7. At operation, multiple or complicated tracts were found in 56 patients and a simple or single cavity in 53.

In the previously reported series the average healing time was 29.3 days. The technique at that time consisted of removing most of the lateral sac wall. The same method was performed in the first 32 patients of the present series with an average healing time of 25.8 days. Since granulation tissue quickly obliterates the lining of the sac, several adjunctive procedures were tried. After routine marsupialization, through and through stainless steel sutures were inserted. These sutures were tightened about a week after operation. The time of healing in 11 patients averaged 24 days. Another technique tried was marsupialization and immediate pinch grafting. The healing time in three such patients was 22 days. It was concluded that these adjunctive procedures had no advantage over the technique finally adopted in 1954 in which all the sac except one fourth inch was removed. The average healing time in 63 patients was 23.6 days. One patient in this last group had a healing time of 85 days, and one other, 124 days. And these two cases of prolonged healing been excluded, the average healing time would have been 21 days. In both of these patients there was a small unhealed area near the anus which finally was closed with wire sutures. Delayed healing was probably caused by proximity of the wound to the anus, repeated trauma to the area, and the obesity of the patient.

The postoperative course is usually uneventful. Pain and discomfort is minimal and healing occurs rapidly.

After complete healing had occurred, one patient developed an adhesive tape dermatitis followed by severe generalized furunculosis involving the buttocks and the scar. Another patient developed maceration of a superficial wide scar because of obesity, excessive moisture, and lack of personal cleanliness. A rather unusual situation in which the entire wound split open occurred one year after operation in one patient and shortly after operation in another. These will be classified as recurrences despite the fact that there was no evidence of sac or sinus tract. It was believed that local trauma or spreading of the buttocks might have contributed to this phenomenon, and in one patient a factitial element was suspected. The latter patient was transferred to another station before complete healing occurred. The other patient was healed by simple, routine measures.

#### DISCUSSION

The exteriorization or marsupialization procedure removes some of the shortcomings of primary closure techniques, such as the fre-

quent failure of primary union, the high rate of recurrence, and the prolonged constipating bed rest regimens. Excision and open packing procedures have the disadvantage of a prolonged healing time averaging three to four months, and the attendant discomfort of frequent dressings. The advantages of the modified marsupialization or exteriorization procedure may be listed as follows:

- (1) The procedure has universal applicability despite the size of the cyst, number of extensions, recurrences, or all other complications.
- (2) Local anesthesia is used for the procedure with a minimal loss of tissue and with adequate visualization of accessory tracts.
- (3) The morbidity is minimal.
- (4) The patients are ambulatory and almost unrestricted activity is permitted.
- (5) The patients are able to return to duty quickly and thus replacement is unnecessary.
- (6) The recurrence rate is low.
- (7) The scar is well healed, pliable and nontender, and the intergluteal contour is preserved.

The modified marsupialization or exteriorization procedure for treatment of pilonidal sinuses has been performed on a total of 182 patients in the outpatient department of this hospital. The first 73 cases have been previously reported. In the last 63 cases the healing time has been shortened to 23.6 days by leaving in situ only a small strip of the sac wall to which the skin is sutured. This series is the largest reported in which such an operation is carried out as an outpatient procedure using local anesthesia and with the patient ambulatory. This outpatient procedure has released hospital beds urgently needed for the treatment of more serious conditions. From the standpoint of cost and the number of man days saved it has benefited the government tremendously.

# CAVITY PREPARATION BY ULTRASONIC VERSUS ROTARY INSTRUMENTATION

## *In Vitro Cutting Effectiveness and Heat Production*

JACK L. HARTLEY *Major USAF (DC)*

**D**URING recent years considerable research has been directed toward the evaluation of new devices and techniques for the removal of tooth structure. Those innovations have been based primarily upon the fact that a higher rotational rate produces increased operating efficiency.<sup>1-3</sup> As rotational rate increases, there is an associated marked reduction in the amount of pressure necessary for cavity preparation and an increase in vibration frequency that results in a procedure less objectionable to the patient.<sup>4-6</sup> Higher rotational speeds produce temperature elevations that should be counterbalanced by cooling sprays of water and air directed within the operational field.<sup>7-9</sup> Although investigators have pointed out the advantages of the high speed techniques, many operators persist in using the time tested, low rotational speeds. In most instances this is due either to personal preference based upon a long period of satisfactory accomplishment with this technique or to the fact that some patients have found higher speeds objectionable.

A comparatively recent development in the field of operative dentistry instrumentation utilizes ultrasonic vibration, along with an abrasive slurry of aluminum oxide, for the removal of enamel and dentin. Reports in the literature cite that little pressure is required and that the very high frequency of vibration results in excellent patient tolerance, pulpal damage appears to be no greater than that caused by conventional rotary instrumentation.<sup>10-11</sup> Evaluation of newer devices and techniques by the U. S. Air Force Dental Service has been carried out and is continuing at the National Bureau of Standards and at this school, in an effort to determine operative techniques and equipment which will remove tooth structure with a maximum of effectiveness and a minimum of objectionable sequelae.

This study was designed to compare in vitro cutting effectiveness of rotating instruments at 400 rpm at 12 000 rpm and an ultrasonic instrument with a frequency of 29 000 cycles per second Simultaneous temperature measurements of the pulp chamber were accomplished throughout the experiment

### METHODS

Three basic instruments were employed in this investigation

1 A conventional dental engine modified by speed reduction pulley to produce a maximum bur speed of 400 revolutions per minute This high torque instrument could not be stalled by normal methods Conventional burs produced good cutting effectiveness but the life of the bur was exceedingly brief owing to the comparatively heavy pressures necessary for cavity preparation

2 A dental engine fitted with a high speed pulley which produced a maximum of 12 000 rpm at the bur This speed was selected because burs of current design produce their most effective results at this rate <sup>1</sup>

3 An ultrasonic dental instrument \*

The time required for cavity preparation was recorded by an electronic switch and chronometer mechanism designed for use with any of the three instruments The timing mechanism was energized by pressure upon the foot control of the instrument under test thus recording only the actual cutting time

Temperature recordings were accomplished by means of copper constantan No 32 gage thermocouples which activated a multiple channel recording potentiometer One thermocouple was placed directly into the pulp chamber of the extracted human tooth while another was placed so as to record the room temperature immediately adjacent to the operative area Pulp chamber temperature elevations above ambient readings were recorded

### PROCEDURE

Sound human teeth which had been extracted for prosthetic purposes or by reason of periodontal involvement were placed immediately in a Deepfreeze It was postulated that this rapid freezing would best preserve the hard and soft tissues until a sufficient number of sound teeth were collected for an experiment of this magnitude While still frozen, the teeth were mounted in artificial stone in the conventional mandibular and maxillary arch forms

A total of 150 cavity preparations were accomplished in the following manner For each of the three methods (i e low speed

---

\* This cavity preparation was purchased from the Cation Equipment Company, Long Island City, N. Y., New York

high speed, and ultrasonic) 10 Class I cavities were prepared in the bicuspid teeth and 10 Class I in the molar teeth. Ten Class V cavities were prepared in the anterior teeth, 10 in the bicuspids, and 10 in the molar teeth. The teeth selected were basically sound in that they did not contain carious areas greater than the early involvement of pits and fissures. Variations in the operational techniques were minimized by adherence to the following factors:

- 1 All procedures were accomplished by the same operator.
- 2 Preparations were standardized in outline form for each type of tooth.
- 3 Depth of cavity was controlled by the principles of correct resistance and retention form.
- 4 The operative technique was accomplished as nearly as possible as though for an actual case.
- 5 A cooling spray of water and air was employed while cutting at 12,000 r.p.m.

Figure 1 Comparison of heat production and actual time of cutting by the three techniques in Class I cavity preparations bicuspid teeth.

## RESULTS

Table 1 summarizes the results of the experiment. All three methods of instrumentation are plotted in bar graph form for each type of tooth and cavity preparation (figs. 1-5). The peak tem

### DISCUSSION

Different working pressures and methods of procedure were necessary in cavity preparation with the three techniques tested. The low speed, high torque procedure very similar to hand instrumentation required a very heavy pressure that frequently led to hand fatigue. Initial penetration of healthy enamel was difficult. The amplitude of vibration appeared very high. The basic

## CAVITY PREPARATION

51

frequency was calculated to be below the range of 1000 to 2000 cps determined by Walsh and Symons<sup>1</sup> to produce the most unpleasant sensation (Revolutions per minute of the handpiece and belt)

High speed instrumentation resulted in a marked reduction in hand fatigue because a much lighter hand pressure was required. Difficulty was experienced in controlling the instrument during the initial phases of cavity preparation due to the tendency to manifest when healthy enamel was removed. Although diamond instrumentation would be far more desirable for this phase of cavity preparation this study did not include the use of diamonds in an effort to evaluate the operating time of cutting without the diamond instrument as a basis for future studies.

An annoying high pitched whine was audible while operating at 12 000 r.p.m. The cooling spray exerted a soothing effect on the noise and functioned effectively in providing improved visibility by removing debris from the operative field. Preliminary studies carried out without the spray but with a stream of air directed upon the dry tooth indicate that the air stream provides maximal visibility during the removal of tooth structure. However, maximal cooling is achieved by a water air spray.

Utilization of ultrasonic instrumentation required no specific additional training, but, optimal operating efficiency could not be attained until the operator developed proficiency in the execution of an exceedingly light hand pressure. Purposeful, but excessive heavy hand pressure was applied to test the effectiveness of the cutting effectiveness was markedly diminished and the heat produced at the cutting tip was so intense that a brown black burn was produced in the dentin.

Visibility was very poor with the ultrasonic instrument. The abrasive slurry rapidly filled the cavity and obliterated the operative area. As a consequence frequent water flushes had to be carried out during the cutting procedure.

Two objectionable effects resulted from rapid wear of the cutting tip (1) Minute particles of metal, abraded from the tip, darkened the slurry and reduced visibility even further, and (2) rounded edges of the worn tip precluded the formation of sharp line and point angles.

To produce these requisites of proper cavity preparation, a new cutting tip had to be inserted. Changing the cutting tip was a time consuming procedure which required the following steps:

- 1 The worn tip was unscrewed

perature rise above ambient appears on the vertical axis. Total cutting time for each type of preparation appears on the horizontal axis.

### DISCUSSION

Different working pressures and methods of procedure were necessary in cavity preparation with the three techniques tested. The low speed, high torque procedure, very similar to hand instrumentation, required a very heavy pressure that frequently led to hand fatigue. Initial penetration of healthy enamel was difficult. The amplitude of vibration appeared very high. The basic

in the bicuspid and molars required an average of 2.1 minutes at 400 r p m. Class I cavities in the bicuspid and molars required an average of 2.5 minutes.

High speed instrumentation required an average of 1.7 minutes to cut Class V cavities in the anterior teeth. The bicuspid and molar teeth required an average of 2.0 minutes for the preparation of Class V cavities at 12,000 r p m. Class I cavities in the bicuspid and molars required an average of 2.5 minutes at the high speed.

Ultrasonic cutting with the abrasive slurry averaged 2.4 minutes for Class V preparations in the anterior teeth and 2.0 minutes for Class V preparation in bicuspid and molars. Class I cavities required an average of 2.2 minutes for preparation of bicuspid and molars by the ultrasonic technique.

2 The threads within the handpiece were cleaned by dipping the end of the handpiece into 70 per cent alcohol and retuning so as to produce resonance while in the alcohol

3 The threads were then blown dry

4 After the new tip was screwed into place the handpiece was retuned

During the latter part of the experiment it was found that the tip could be reshaped by grinding with a rotary hand instrument sharpener This procedure was entirely satisfactory and reduced the time lost considerably Although the tuning procedure was not difficult the time involved in reshaping or changing the tips of the ultrasonic instrument exceeded that necessary to exchange burs in the conventional handpiece

Considerable difficulty was encountered in maintaining control of the ultrasonic handpiece because of an unbalanced weight distribution The absence of rotational torque completely obviated any "walking" tendencies, but the weight exerted on the hand piece by the attached heavy tubing made it difficult to control the handpiece during precision cutting procedures It was necessary to observe stringent precautions to assure the removal of only the desired areas Very exact control of the handpiece could be maintained if a semiflexible upright support were attached to the top of the machine console to bear the weight of the tubing

The actual time involved in cutting procedures, when the ultrasonic instrument was used in cavity preparation compared favorably with the two rotary procedures However the over all time required for cavity preparation—including tuning the handpiece changing tips, and flushing the operative field—was somewhat greater than that required in the conventional technique Data on this phase of the evaluation are not presented because to be of value they should include results of actual clinical studies after further familiarization with the instrument

#### SUMMARY

Temperatures produced within the pulp chambers of anterior bicuspid and molar teeth, when cavities were prepared by low speed high speed and ultrasonic instrumentation ranged from a minimum average temperature rise of  $1.9^{\circ}\text{C}$  in molars following ultrasonic preparation to a maximum average rise of  $10.0^{\circ}\text{C}$  in anteriors prepared by high speed rotary instrument technique

The possibility of heat damage to the pulp during ultrasonic instrumentation properly employed appears to be no greater than with conventional rotary instrumentation

The average time required to prepare anterior Class V cavities with low speed instrumentation was 2.3 minutes Class V cavities

were not certain. In the whole series, 10 patients gave a family or personal history of atopy.

### HOSPITAL STAY

Complete blood counts, urinalyses, and sedimentation rates were obtained for 59 of the 68 patients. In this group of 59, the average hospital stay was 5.9 days. The range was from 2 to 10 days, except for two patients who stayed for 22 and 28 days, respectively. There was little apparent difference in the number of days of hospitalization between those who had taken penicillin orally and those who had received intramuscular injections. All patients were discharged from the hospital when they had been free of symptoms for 24 hours. Four were later readmitted in relapse after strenuous physical activity. Many other patients undoubtedly had minor relapses, but not severe enough to necessitate rehospitalization.

### CLINICAL PICTURE

Of the 68 patients studied, 14 had mild or severe angioneurotic edema, 20 had transient urticarias of the typical "hive" type, 7 developed the so-called fixed urticarias, and 25 presented a picture of typical erythema multiforme like reactions (fig. 1). One of these patients developed large bullae at the site of the urticarial lesions (erythema multiforme bullosum). Five patients developed purpura, in two this appeared to be primary, and in three the purpura was secondary to severe urticarial lesions. One patient, who had no atopic history or background, developed a fine papular eruption in the flexural folds. This subsided completely in three days. Another patient developed a mild anaphylactoid shock type reaction with angioneurotic edema about the face within 20 minutes after ingestion of the first penicillin tablet. Joint pain and swelling were present in 41 of the 68 patients, and 7 were initially admitted to the hospital with the provisional diagnosis of rheumatic fever with joint pains, tachycardia, and urticarial skin eruptions. Four other patients initially developed morbilliform eruptions and temperatures and were admitted to isolation wards with the provisional diagnosis of rubella. Thirty-four patients had temperature elevations of over 100° F orally.

On admission to the service, the patients were given in rotation either a placebo, an antihistaminic, or 20 units of corticotropin (ACTH) intravenously, and all were placed on bed rest. Those who received the placebo progressed as well as those given an antihistaminic or ACTH. Four patients with extremely severe reactions and discomfort were given cortisone orally. The patients on cortisone treatment were discharged within 24 hours after the subsidence of their reactions, as were the others, however, they

# REACTIONS TO PROPHYLACTICALLY ADMINISTERED PENICILLIN

A Study of Sixty Eight Hospitalized Patients

KENNETH H BURDICK *Captain USAF (MC)*

**I**N RECENT years many articles reporting allergic reactions to penicillin have appeared<sup>1-4</sup>. Unfortunately many of the reports deal with persons receiving penicillin therapeutically for various diseases and the clinical picture and reported laboratory findings of the allergic reactions have been modified by these illnesses. In a recent attempt to abate an epidemic of streptococcal disease at this installation, the entire military population, with the exception of those persons on leave or those suspected of being allergic to penicillin were given prophylactic penicillin. This study deals only with those persons requiring hospitalization for severe reactions of an allergic nature in whom reactions from other drugs foods or illness were excluded by history and by physical examination. The scope of this article has been limited to an attempt to correlate the clinical picture with the changes in common laboratory results and to relate those to the number of days of hospitalization and the length of the incubation period.

## OBSERVATIONS

Penicillin was administered prophylactically to 13 113 persons, potassium penicillin G was given orally to 7 307 in a dosage of 313 5 mg (500 000 units) a day for 10 days while 5 806 received either 495 5 mg (600 000 units) or 743 2 mg (900 000 units) of benzathine penicillin G intramuscularly. During the six week period of this study, 68 of the 13 113 (0 5 per cent) were admitted as patients who filled the above criteria. Of the reactions in the patients, 52 followed intramuscular administration of penicillin and 16 followed oral administration. Fifty of the patients stated that they had received penicillin before this study. Eleven stated they had not taken penicillin previously in any form and so

Sedimentation rates, determined on 59 patients, were divided into three groups—those from 1 to 10 mm/hour, those from 11 to 20 mm/hour, and those above 20 mm/hour. Sedimentation rates of the patients in each group were compared with the average days of hospitalization, leukocyte count, and febrile reaction (table 1). Of the 59 patients, 37 had sedimentation rates of over 10 mm/hour, with 21 patients having sedimentation rates of over 20 mm/hour. Nine of these were above 30, the highest being 48 mm/hour. Grouping these patients by sedimentation rates and comparing these rates with the average days of hospitalization revealed that there was little relationship between sedimentation rate and length of hospitalization. No significant conclusions could be drawn concerning the relationship between oral administration of penicillin and elevation of the sedimentation rate.

TABLE 1 *Relationship of sedimentation rate to leukocytosis, elevated temperature, and length of hospitalization of 59 patients.*

Sedimentation rate (mm/hr)	Number of patients			Days in hospital		Leukocytosis		Fever	
				Average	Range	Number	Percent	Number	Percent
1-10	22	Injection	16	6.6	2-10	10	46	10	46
		Oral	6	5.8	3-9				
11-20	16	Injection	11	5.4	2-9	6	38	12	75
		Oral	5	4.0	3-5				
21 plus	21	Injection	20	6.3	3-9	13	62	12	57
		Oral	1	4.0					
Total	59	Injection	47	5.9		29	49	34	58
		Oral	12						

One was 22 days

One was 28 days

Leukocyte and differential blood counts were reported for 59 of the patients. A leukocytosis exceeding 10,000/ $\mu$ l was found in 29 cases, the highest being 18,000/ $\mu$ l. Table 1 indicates that there was little association between leukocytosis and sedimentation rates. Differential counts were not abnormal, only one patient showing a significant elevation of the eosinophil count.

## CLINICAL FINDINGS

Thirty four patients showed febrile reactions of over 100°F. It is interesting to note from table 1 that there was no apparent relationship between the number of patients with fever and the extent of elevation of the sedimentation rate.

As shown in figure 1 41 patients had joint pain and/or swelling of the joints at some time during their hospitalization. We were unable to demonstrate any apparent relationship between the presence of joint involvement and either the number of days' hospitalization or the degree of elevation of sedimentation rate.

**Reaction Time** For the 52 patients who had received benzathine penicillin G intramuscularly the time from the injection to the beginning of allergic symptoms averaged 10.3 days with a range of 1 to 21 days. There was no apparent relationship between the degree of elevation of sedimentation rate and the time of onset of symptoms. Although it has been thought that a prolonged incubation period may be followed by a more severe and longer lasting allergic reaction we were not able to demonstrate that those with long incubation periods spent more days in the hospital than those with short ones. The patients were divided into three groups by the number of days from injection to development of symptoms. As may be seen in table 2 38 (73 per cent) of the 52 were in the 4 to 14 day group. There were 7 in the 1 to 3 day group and 7

TABLE 2 Incubation periods of penicillin reactions and length of hospitalization in 52 patients receiving penicillin intramuscularly

	Group 1	Group 2	Group 3
Number of patients	7	38	7
Number of days between injection of penicillin and reaction	1.3	4.14	15.21
Days hospitalized	6.0	5.3	5.0

in the 15 to 21 day group. Contrary to our previous clinical impressions the reactions of the latter group were neither more severe nor longer lasting than those in the other groups.

## SUMMARY AND CONCLUSIONS

This study attempted to associate the severity of prophylactic penicillin reactions with common laboratory studies. Certain clinical observations and incubation periods. No association was evident in terms of average days of hospitalization between sedimentation rate, leukocytosis or fever. In those

patients with elevated sedimentation rates there was no association with the presence or absence of joint involvement, fever, or elevated white blood cell count. The time interval between injection of the drug and appearance of symptoms (incubation period) had little bearing on the length of hospitalization. In these hospitalized patients, reactions from benzathine penicillin G were apparently no more severe or prolonged than those from penicillin given orally.

It must be emphasized that the presenting symptoms and laboratory findings in many of these patients may closely simulate those of acute rheumatic fever and/or several of the exanthemata.

# THE ISOLATION OF ENTERIC PATHOGENS AT BARROW, ALASKA

JACK T. CULLISON *Technical Sergeant, USAF*  
THOMAS R. A. DAVIS *M. D.*

**R**EPORTS of gastroenteric diseases in Alaska though common and substantiated by observation have not received adequate epidemiologic study. In 1953 Pauls<sup>1</sup> stated that outbreaks of diarrheal diseases commence during the spring "breakup" and continue throughout the summer. The peak of incidence during this period is not known and an evaluation of the true incidence and severity of such disturbances is difficult because cases are poorly documented, containing little information as to the specific causes of the disease. In 1950 Williams<sup>2</sup> published a list of *Salmonella* and *Shigella* organisms isolated in Alaska indicating the presence of a number of types of both groups. Early reports<sup>3,4</sup> cited outbreaks of typhoid and paratyphoid occurring at Barrow, Alaska and blamed water as the means of transmission. Because of the sporadic distribution of cases, a recent study<sup>5</sup> throws some doubt on the involvement of water as a means of transmission.

During the months of November 1954 and February and July 1955 this laboratory had opportunities to conduct studies of enteric pathogens among the Eskimos at Barrow, Alaska. This study was initiated to determine the possible influence of the enteric disease problem in Alaska on military personnel stationed in remote areas.

Barrow, an Eskimo village situated on the northernmost tip of the Alaskan Territory in 71° 21' north latitude and 156° 17' west longitude is composed of some 1,200 Eskimos. This particular village was selected because it was believed to be typical of most coastal villages, and many of the facilities required for this study were available at the Alaska Native Service Hospital.

---

From Arctic Aeromedical Laboratory, Land Air Force Base, Alaska. Ser. Cullison is now assigned to U. S. Air Force Hospital, Parks Air Force Base, Calif. and Dr. Davis is with the U. S. Army Medical Research Laboratory, Fort Knox, Ky.

## METHODS AND RESULTS

fecal specimens were collected in 4 ounce ointment containers which had been distributed to the natives through the Alaska Native Service Hospital personnel. Response was good, and a total of 240 samples were collected.

The preliminary bacteriologic examination consisted of introducing 1 gram of feces into tetrathionate or selenite F enrichment broth and incubating for from 18 to 24 hours at 37°C. Specimens were then transferred to *Salmonella* Shigella (SS) agar plates and again incubated for a period of 24 hours at 37°C. Suspicious colonies were then transferred to nutrient agar slants, incubated, and returned to this laboratory for further investigation.

Generic identification was based upon their cultural and biochemical reactions in Kligler's iron agar, SS agar, together with the absence of urea production and their reaction in various carbohydrate fermentation media. Organisms displaying characteristics for *Salmonella* or *Shigella* were then typed with *Salmonella* polyvalent serum, grouping sera, and *Shigella* grouping sera.

Thirty six isolations of *Salmonella typhimurium* and one of *Shigella sonnei* were made from the fecal examinations. None of the natives had diarrhea during the samplings, thus the organisms represent a subclinical or carrier state.

Ten of the samples obtained in February 1955 were from individuals who had been previously sampled during the preceding November. Four of these subjects were found to possess *S. typhimurium* in November, but not in February. Two individuals were found to have this organism in both November and February. The subject positive for *S. sonnei* in November was negative in February.

Numerous cultures of paracolon organisms, most of which belonged to the *Hafnia* group, were isolated. At the present time the pathogenicity of the paracolon group is debatable, and an evaluation of the part they play in the gastrointestinal diseases must await further studies. However, the present evidence indicates that they may produce disease under certain conditions.

Results of the cultures are given in table 1. Ages of the individuals from whom samples were taken varied from 22 days to 75 years. This number represents the combined number of individuals from each of the three sampling periods. Age distribution agrees with other records of incidence of these organisms in that well over half the number of positive cultures occurred in the first two age groups.

Significance of difference between winter and summer

Combined significance for 20-49 year age groups P < 0.1

W winter S summer

As soon from table 1, a significant difference between winter and summer samples existed in the 20- to 29 year age group. These statistical differences were computed by the chi square method with corrections applied for small sampling numbers where appropriate.

### DISCUSSION

The table shows that in all age groups carrier rates were high, and no demonstrable clinical symptoms in any of the people investigated could be elicited. Because of the seasonal variation of this rate together with the fact that many of the individuals who were positive in the summer were negative in the winter, it is questionable that the use of the term "carrier" is applicable to the *Salmonella* picture demonstrated in Barrow. It is perhaps more accurate to consider the presence of *Salmonella* in the stool specimens either as the residuum of a recent clinically demonstrable infection or as evidence of subclinical infection. This would suggest that, at Barrow, reinfection of the community goes on throughout the seasons and that the rate is altered by the influence of seasonal change on the total availability of the infecting organisms. The practice in coastal villages is to obtain a water supply in the summer from sources which are easily contaminated by unhygienic practices of garbage and human waste disposal. In the winter, the water supply at Barrow is stated to be obtained by cutting ice blocks from a nearby lagoon. This may be true in many instances, but personal observations have shown that much of the water supply is obtained by melting snow collected from the immediate vicinity of the home, where dog teams are tethered and where human waste is thrown from "honey buckets." Thus continuous reinfection of the population can occur. This in turn produces a high immunity rate in the community, which could produce the sporadic appearance of clinical cases difficult to correlate as to method of transmission. *Salmonella* studies by this laboratory in the canine population of Barrow have shown rates of infection similar to those demonstrated for humans in this report.<sup>5</sup>

The study reported here does not show the presence of *Salmonella typhosa* or any other members of this genus. Since other studies have reported outbreaks labeled typhoid and associated with some reports of isolation of the organism,<sup>2-4</sup> the lack of such evidence in our study may be due to the sampling inadequacy. Only one isolation of *Shigella* was found, and a second sample from this individual three months later was negative. Again this may be due to the limitations of the methods used in this study.

This report adequately demonstrates the importance of enteric diseases in an arctic village. Their impact on the morbidity and mortality of the population is not known because of the difficulties of being on the spot at the right time and the inadequacy of existing records. In another similar study at Fort Yukon, there was found to be a high incidence of diarrheal disturbances in the 0 to 9 age group occurring eight times oftener than in any other age group.

With the exception of *S. sonnei*, it is unlikely that the enteric pathogens as found here will seriously affect the well being of military personnel. The military practice of immunization and the existence of cross immunization together with reasonable sanitation measures will afford protection. However mild gastro enteric disturbances in military personnel in the arctic do occur and the influence of these on over all operational efficiency is a factor to be considered.

### SUMMARY

Investigation of the population of Barrow for salmonellosis shows a relatively high incidence of the causative organism in all age groups. A seasonal variation is demonstrated with about a 100 per cent increase of isolations in the summer as compared with those in the winter. The implications of these findings are discussed.

**ACKNOWLEDGMENTS** The technical assistance by Sergeant E. D. Pace and Airman First Class S. D. Slevin and the co-operation of the personnel of the Alaska Native Service Hospital at Barrow are gratefully acknowledged.

# IMPROVING PREDICTABILITY OF MINNESOTA MULTIPHASIC PERSONALITY INVENTORY

GERALD J. BRISKIN *First Lieutenant USC USAR*  
JAMES A. STEVENS A B

OVER a period of two years in our particular setting, a mental hygiene clinic on a military reservation, we have become increasingly aware of a discrepancy between diagnostic statements made from the Minnesota Multiphasic Personality Inventory (MMPI) and the final diagnosis arrived at by joint staff efforts. The MMPI profiles consistently indicated that the patients were sicker than they appeared either clinically or by other psychologic instruments.

This discrepancy appears to be the result of differences between the population of this particular Army post and the population on which the MMPI was standardized. We are dealing with an essentially younger population (mean age 22 years, standard deviation 3.84 years) in a setting in which illness can bring strong secondary gain such as light duty, hospitalization, dismissal of possible courts martial charges, and even release from service.

Our intent in this study was to revalidate the MMPI for the specific population with which it was being used.

## METHOD

An attempt was made to increase the predictive ability of the MMPI by revalidating it to conform more readily with the specific population with which it was being used. This was accomplished by (1) determining the means and standard deviation for each of the subscales of 80 MMPI profiles selected at random from our files and (2) recalculating the T scores for the population being studied. To fix the average score at 50 this standardization (table 1) was accomplished by use of the following formula:

$$T = 50 + \left( \frac{\sum \bar{X}}{S} \right) 10$$

---

From Mental Hygiene Consultation Service, Fort Campbell, Ky. Dr. Briskin is now at Byron Harless and Associates, 420 West Lafayette Street, Tampa, Fla.

Twenty four MMPI profiles were next selected at random from the files. None of these records had been included in the above samples. Using the usual precautions to control for bias, two experienced clinicians then interpreted them attempting to place them in one of the following diagnostic categories: normal, neurotic, psychotic, and character and behavior disorder.<sup>2</sup>

TABLE 1 *Revalidated means and standard deviations of the subscales of the MMPI for the Fort Campbell population*

Subscale	Mean	Standard deviation
7	47.95	24.59
L	4.44	2.68
F	11.78	9.67
K	12.08	5.13
Hs	12.93	7.23
D	27.37	8.00
Hy	27.31	7.10
Pd	26.25	6.35
Mf	23.23	5.65
Pa	13.36	7.80
Pr	23.80	11.70
S	27.13	15.25
Ma	19.78	5.90

These 24 records were then replotted using the T scores determined above and again interpreted in terms of the four scoring categories. Chi squares were then calculated to determine whether or not the clinicians were in significant agreement with each other.

Each of the clinician's judgments from both the standard MMPI data and the revalidated data, were compared to the final diagnosis (table 2) and tested by chi square. The final diagnosis of the patient was arrived at by psychiatric interviews, a complete battery of psychological tests, and a social history.

### RESULTS

Table 3 summarizes our findings. Dealing with standard MMPI's the judges agreed diagnostically on 15 cases and disagreed on 9. The chi square of their agreement is 18.00 and is significant at the 0.001 level.

TABLE 2 *Summary of data*

Case	Standard MMPI		Revalidated MMPI		Final diagnosis
	Judge 1	Judge 2	Judge 1	Judge 2	
1	Ne	Ne	Ne	Ne	P
2	C	Ne	C	C	C
3	P	P	C	C	C
4	P	P	C	C	C
5	No	No	Ne	C	C
6	P	P	P	C	C
7	P	P	P	P	C
8	C	C	C	C	C
9	P	Ne	C	C	Ne
10	Ne	Ne	Ne	Ne	C
11	P	C	C	C	C
12	Ne	Ne	Ne	Ne	C
13	P	C	P	P	C
14	P	P	Ne	Ne	Ne
15	Ne	Ne	Ne	Ne	C
16	P	No	No	No	C
17	Ne	C	C	C	C
18	C	No	C	C	C
19	C	No	No	No	C
20	Ne	Ne	C	P	No
21	P	C	C	C	C
22	P	P	C	C	C
23	P	P	C	C	P
24	P	P	C	C	C

No = Normal

Ne = Neurotic

P = Psychotic

C = Character and behavior disorder

However, in predicting the final diagnosis from standard MMPI's, judge 1 was correct in only 5 cases and judge 2 was correct in 7 cases. These results, when tested by chi square, are purely chance.

When the revalidated MMPI profiles were used, the judges agreed diagnostically on 21 cases and disagreed on 3. This is significant at the 0.001 level. In predicting the final diagnosis, the two judges were able to do so successfully in 11 and 13 cases respectively, and these findings reach significance at the 0.02 level or better.

TABLE 3 Chi squares showing significance of agreement between judges and final diagnosis

	Agreement between judge		Agreement between judge 1 and final diagnosis		Agreement between judge 2 and final diagnosis

	$\chi^2 = 50.00$		$\chi^2 = 5.56$		$\chi^2 = 10.89$	

df = 1

Significant at 0.02 level

Significant at 0.001 level

## DISCUSSION

Psychologists as scientists prefer to utilize as well as place greater confidence in standardized tests. Nevertheless such tests have serious limitations. Because they are so well standardized the tendency is to use them blindly in all clinical settings without regard to the particular population involved. Yet these populations or subpopulations if you will may vary markedly in cultural background, needs, attitudes, or other variables, and these discrepant variables may seriously impair the validity of the test being used.

Certain tests lend themselves to revalidation readily. When such is the case as in this study, revalidation can improve the predictive ability of a test to a significant degree.

It should be pointed out that even though the judges in this study were able to predict the criterion significantly, their combined predictive accuracy was only 50 per cent. Even allowing for errors in the final clinical diagnoses, this predictive accuracy is lower than would be optimally desired. It is suggested that the percentage of correct predictions can be further increased if tests are given in batteries. When the diagnoses based on a test battery for the experimental group are compared to the final clinical diagnoses, the predictive accuracy rises to approximately 79 per cent (agree 19, disagree 5).

Consequently, we conclude that increased predictive ability can be obtained by specific revalidations of the test involved and/or the administration of test batteries

### SUMMARY

An attempt was made to increase the predictive ability of the Minnesota Multiphasic Personality Inventory (MMPI) by revalidating it to conform more readily with the specific population with which it was being used. This was accomplished by determining the means and standard deviations for each of the subscales and then recalculating the T scores for the population being studied.

Making diagnostic predictions on the basis of four categories—normal, neurotic, character and behavior disorder, and psychotic—two judges, using the revalidated data, were able to predict with significant accuracy the final psychiatric diagnosis. When these same judges attempted to predict the final diagnosis, using the standard MMPI profiles, their efforts were on a purely chance basis.

In conclusion, it is believed that the predictive ability of the MMPI can be improved if the test is specifically revalidated for the particular subpopulations with which it is being used.

The method outlined above is suggested for determining local norms which may be used by psychologists employing the MMPI and/or tests of a similar nature.

## Clinicopathologic Conference

U S Naval Hospital Philadelphia Pa \*

### ATAXIA DECREASED VISION UPPER EXTREMITY WEAKNESS

**Summary of Clinical History** Since birth this 25 year old white woman had decreased vision of the left eye with occasional diplopia. She has also had intermittent anorexia for several years with frequent bouts of nausea vomiting and hiccoughing. At the age of 23 when 6 months pregnant she was admitted to another hospital with frequent hiccoughing weakness of the right arm and inability to raise the right hand. A myelogram showed evidence of a central nervous system lesion involving almost the entire cervical canal. A cesarean section was performed with delivery of a living male fetus.

Following discharge from that hospital the patient's condition remained essentially the same although there was an increase in weakness of the right hand and arm. Right occipital and temporal headaches occurred at more frequent intervals and she lost 40 pounds. She did not consult a physician in the two years since her discharge from the other hospital. She was admitted here at the age of 25 years and weighing 91 pounds.

**Physical Examination** On admission the patient was a fairly well developed but emaciated woman appearing her stated age of 25 years. The pupils were round regular and equal and reacted to light and accommodation. Extra ocular movements were

Capt Ch 1 s L Fergus n MC USN Command g Officer Fr m th N u r s u r g c l  
Service Lt N a l l A r n u MC USNR Ch f

normal Visual acuity was markedly diminished in the left eye. Funduscopy was unsatisfactory, but dilated tortuous veins were seen in the left eye, and in the medial part of the retina several small rod spots were noted. There was tenderness on percussion and palpation of the posterior aspect of the neck from the atlas to the 7th cervical vertebra. No lymphadenopathy was noted. Lungs were clear to percussion and auscultation. The heart was normal in size, position, rate, rhythm, and force. No murmurs were heard. The abdomen presented a well healed midline cesarean section scar. There was an orange sized mass in the epigastrium and periumbilical region, which was apparently freely movable but firm and nontender. A neurologic examination showed marked weakness of the right hand, forearm, and arm, moderate weakness of the left hand and arm, and atrophy of the muscles of both hands. The gait was slightly ataxic, and there was a negative Romberg sign. Concentric contracture of the visual fields of the left eye, greater in the temporal fields, was noted. Vibratory and position senses in the right upper extremity were absent. The lower extremities showed hyperactive deep tendon reflexes throughout. Hoffmann's sign was positive on the right.

**Laboratory Studies** A lumbar puncture revealed that cerebrospinal fluid pressure was 140 mm, which was elevated to 310 mm by abdominal straining and to 230 mm by bilateral jugular compression. Six milliliters of clear, slightly xanthochromic fluid was removed. Cerebrospinal fluid protein was 10 to 20 mg/100 ml. Blood studies revealed the hemoglobin to be 13 g/100 ml, the white blood cell count and differential were normal. The Kahn test was negative, and the blood sugar and blood urea nitrogen were within normal limits. Urinalysis showed no abnormalities.

**Course in Hospital** One month after admission to this hospital a laparotomy was done, at which time a firm mass 5 cm in diameter was excised from the tail of the pancreas. This specimen consisted of a fibrous walled cyst with calcification, external to which was a moderate amount of pancreatic acinar tissue showing minimal inflammatory and fibrotic changes. A diagnosis of fibrous cyst was made.

The patient was seen by a neurosurgical consultant, and at his suggestion a ventriculogram was recommended prior to attempting surgical laminectomy in an effort to alleviate the symptoms of central nervous system disease. A ventriculogram was carried out successfully, however, the patient became extremely restless following the procedure. Amytal Sodium (brand of mephobarbital sodium) was given. Respirations slowed to three to four per minute, and the patient became comatose and died about four and one half hours later.

## DISCUSSION

Doctor Aronson One is always tempted in dealing with a clinical problem to seek a common denominator which will explain diverse and seemingly unrelated findings In the case at hand that approach is too attractive to ignore In this protocol we are presented with a young woman who is afflicted with disease in several organs She has disturbed vision in her left eye which is apparently due to some congenital or perhaps familial disease in the globe as it has produced lifelong disturbance in vision associated with a vascular anomaly of the fundus

In addition we are told that she has a lesion of the cervical spinal cord There is ample evidence of this clinically and the marked sensory disturbance atrophy and weakness in the upper extremities and spasticity in the lower would strongly suggest that it is intramedullary tending to be somewhat right sided in location Further there apparently is irritation either of the phrenic centers in the cervical cord or perhaps of the visceral centers of the medulla It could be that the process extends upward to the medulla The additional findings of headache and ataxia suggest the possibility of a second lesion in the posterior fossa as a possible cause of the vomiting hiccoughing headaches and equilibratory disturbance which she exhibits One could predicate cerebellar lesion compressing the 4th ventricle and medulla and thus producing obstructive hydrocephalus and irritation of medullary centers The lack of involvement of the lowermost cranial nerves would suggest this possibility rather than that of an intramedullary process from the cord to the medulla because the latter would produce in all probability lower motor neuron involvement in the distribution of those nerves whose nuclei lie in the medulla There is little or no evidence in the protocol which would point to a supratentorial brain lesion as a cause of these findings

Finally we are told that a pancreatic cyst was found and removed at patoromy Although I may be going far afield it seems necessary to tie all the findings together into a single syndrome one of the so called macularoses Specifically I refer to the nosologic entity known eponymically as Lindau von Hippel disease Angiomatosis retinae was described by von Hippel<sup>1</sup> in 1904 One or both eyes may be affected One sees large tortuous veins which often contain bright red blood and are accompanied by a large artery which shows beading and variations in caliber The vessels lead to rounded nodules usually situated in the periphery of the retina and believed to be hemangioblastomas

Lindau<sup>2</sup> in 1926 established a relationship between cerebellar and retinal tumors He showed that a tumor histologically similar to that found in the retina could be found in the cerebellum These tumors were hemangioblastomas (occasionally known as hemangioendotheliomas) and were frequently cystic He pointed out that many lesions previously diagnosed as benign cysts or gliomatous cysts of the cerebellum were actually hemangioblastomas with a small mural nodule of tumor surrounded by a large cyst whose wall consisted of glia and that the tumor

nodule was often missed. In addition to the retinal lesions which occurred in relatively few cases there were not infrequently hemangioblastomas of the brain stem and spinal cord, epithelial cysts, angiomas and cystadenomas of the pancreas, cysts and angiomas of the liver, spleen and kidneys, tumors resembling hypernephromas of the kidney, paragangliomas and adenomas of the adrenals, cystadenomas of the ovaries, cysts of the epididymis, and in rare instances cutaneous nevi.

Significantly only a very few hemangioblastomas have been found above the tentorium. In this connection the embryologic work of Streeter<sup>2</sup> should be mentioned. He pointed out that the primitive vascular plexus differentiates slowly into arteries, veins and capillaries early in development, and that during this phase true vascular tumors might arise. Karlfors (quoted by Cushing and Bailey<sup>4</sup>) stated that during this same period a very rich vascular plexus consisting of undifferentiated capillaries exists in the posterior fossa and simultaneously a similar condition exists in the eye, thus possibly explaining the frequency of and association between lesions of the cerebellum and retina.

The disease is apparently inherited and seems to behave as a simple dominant characteristic. The onset is usually in childhood or early adult life. Wyburn-Mason<sup>5</sup> enlarged on the spinal cord involvement in the disease, mentioning that sites of predilection were the cervical and lumbar enlargements. Often he states there is an associated syringomyelic cavity which gives rise to the usual signs.

Of course the term syringomyelia is used somewhat loosely by many writers. It is not at all unusual for intramedullary tumors to be associated with large cystic cavities. These cavities usually contain fluid often indistinguishable from spinal fluid. At any rate clinically and myelographically, there appears to be a hemangioblastomatous cyst of the cervical cord in this case.

The spinal fluid protein is usually quite high in these cases of hemangioblastoma. The protocol tells us that the fluid is xanthochromic and the protein 10 to 20 mg/100 ml. I question the validity of these determinations and would be tempted to add a cipher to each. Incidentally Levin<sup>6</sup> states that in every case of Lindau's disease in which the cord was properly examined a spinal tumor was found.

The lesions of the abdominal viscera rarely produce symptoms. The tumors of the kidney that resemble hypernephromas are apparently not malignant. Polycythemia has been reported in several cases but apparently was lacking in this patient. Cramer<sup>7</sup> collected several of these cases and adduced histologic evidence for possible hematopoietic activity in some of these tumors. The cerebellar growths may often be removed unsuccessfully and the spinal and retinal lesions can occasionally be benefited by operation.

Finally our patient appears to have died a medullary death rather suddenly. There is a known propensity for these very vascular tumors to hemorrhage. One can only guess at the final incident but it seems likely that a sudden hemorrhage may have occurred within a hemangioblastomatous cyst of the cerebellum as a result of the upsetting of pressure relations incident to ventriculography.

#### Dr Aronsen's diagnosis

Lindau von Hippel disease with (1) angiomas of retinae left eye, (2) hemangioblastoma of cervical spinal cord probably cystic, (3) probable cystic hemangioblastoma of the cerebellum with obstructive hydrocephalus and possible terminal hemorrhage causing medullary failure and (4) cystic anomaly of the pancreas and possibly of other organs.

#### PATHOLOGIC FINDINGS

Doctor Witz: At autopsy cyanosis was visible and was most marked in the dependent portions of the body and at the extremities the fingers and toes. A well healed lower abdominal scar was present and the hair had been shaved from the scalp. No anomalies were visible. Two bur holes were present in the occipital bones one on each side.

The most important findings were those of the central nervous system. Lying over the right occipital region beneath the dura there was approximately 50 ml of recently clotted blood covering an area measuring 6 cm in diameter and 1.5 cm in thickness. The brain substance was depressed in the area of this hematoma. The other external vessels of the brain appeared normal. A yellowish brown tumor of firm consistency was present in the cervical cord (fig 1). This began just caudal to the 4th ventricle protruding slightly up into it and continued down through the pons and medulla into the first portion of the cervical cord. The entire tumor measured 4 cm in length and 2 cm in greatest diameter. In the region of the 4th ventricle it was solid and yellowish and contained blood. In the pons (fig 2) it was cystic bearing multiloculated spaces with thin walls and smooth linings filled with coagulated semiopaque grayish-white material. In the medulla solid yellow tissue was present. The cervical cord involved by the tumor showed necrosis and much of the tumor had sloughed away leaving a ragged cystic space. A small nodule of tumor was present on the anterior surface of the cervical cord. This nodule was solid and golden yellow.

No involvement of the cerebellum by tumor was seen nor were there any changes in the cerebrum itself. A few minute hemorrhages were present in the cerebrum scattered in several areas. These were interpreted as secondary to encephalography. Microscopic examination showed that the tumor itself consisted of a mixture of small vascular

*Figure 1 Cervical spinal cord showing the partially necrotic hemorrhagic lesion which is continuous with the one in the medulla and pons. The small discrete lesion on the anterior surface of the cord is shown farther toward the caudal end.*

*Figure 2 Coronal sections of the cerebellum and pons showing the location of the centrally placed hemangioma. Recent hemorrhage is present*

Finally our patient appears to have died a medullary death rather suddenly. There is a known propensity for these very vascular tumors to hemorrhage. One can only guess at the final incident but it seems likely that a sudden hemorrhage may have occurred within a hemangioblastomatous cyst of the cerebellum as a result of the upsetting of pressure relations incident to ventriculography.

#### Dr. Aronson's diagnosis

Lindau von Hippel disease with (1) angiomatosis retinae, left eye, (2) hemangioblastoma of cervical spinal cord probably cystic (3) probable cystic hemangioblastoma of the cerebellum with obstructive hydrocephalus and possible terminal hemorrhage causing medullary failure and (4) cystic anomaly of the pancreas and possibly of other organs.

#### PATHOLOGIC FINDINGS

Doctor Watts. At autopsy cyanosis was visible and was most marked in the dependent portions of the body and at the extremities the fingers and toes. A well healed lower abdominal scar was present and the hair had been shaved from the scalp. No anomalies were visible. Two bur holes were present in the occipital bones one on each side.

The most important findings were those of the central nervous system. Lying over the right occipital region beneath the dura there was approximately 50 ml of recently clotted blood covering an area measuring 6 cm in diameter and 1.5 cm in thickness. The brain substance was depressed in the area of this hematoma. The other external vessels of the brain appeared normal. A yellowish brown tumor of firm consistency was present in the cervical cord (fig. 1). This began just caudal to the 4th ventricle protruding slightly up into it and continued down through the pons and medulla into the first portion of the cervical cord. The entire tumor measured 4 cm in length and 2 cm in greatest diameter. In the region of the 4th ventricle it was solid and yellowish and contained blood. In the pons (fig. 2) it was cystic bearing multiloculated spaces with thin walls and smooth linings filled with coagulated semiopaque grayish-white material. In the medulla solid yellow tissue was present. The cervical cord involved by the tumor showed necrosis and much of the tumor had sloughed away leaving a ragged cystic space. Figure 2 Coronal sections of the cerebellum and pons showing the centrally placed hemangioma. Recent hemorrhage

Finally our patient appears to have died a medullary death rather suddenly. There is a known propensity for these very vascular tumors to hemorrhage. One can only guess at the final incident but it seems likely that a sudden hemorrhage may have occurred within a hemangioblastomalous cyst of the cerebellum as a result of the upsetting of pressure relations incident to ventriculography.

#### Dr. Atkinson's diagnosis

Lindau von Hippel disease with (1) angiomas of retinae, left eye, (2) hemangioblastoma of cervical spinal cord probably cystic, (3) probable cystic hemangioblastoma of the cerebellum with obstructive hydrocephalus and possible terminal hemorrhage causing medullary failure, and (4) cystic anomaly of the pancreas and possibly of other organs.

#### PATHOLOGIC FINDINGS

Doctor Watts. At autopsy cyanosis was visible and was most marked in the dependent portions of the body and at the extremities the fingers and toes. A well healed lower abdominal scar was present and the hair had been shaved from the scalp. No anomalies were visible. Two burr holes were present in the occipital bones, one on each side.

The most important findings were those of the central nervous system. Lying over the right occipital region beneath the dura there was approximately 50 ml of recently clotted blood covering an area measuring 6 cm in diameter and 1.5 cm in thickness. The brain substance was depressed in the area of this hematoma. The other external vessels of the brain appeared normal. A yellowish brown tumor of firm consistency was present in the cervical cord (fig 1). This began just caudal to the 4th ventricle protruding slightly up into it and continued down through the pons and medulla into the first portion of the cervical cord. The entire tumor measured 4 cm in length and 2 cm in greatest diameter. In the region of the 4th ventricle it was solid and yellowish and contained blood. In the pons (fig 2) it was cystic bearing multiloculated spaces with thin walls and smooth linings filled with coagulated semiopaque grayish-white material. In the medulla solid yellow tissue was present. The cervical cord involved by the tumor showed necrosis and much of the tumor had sloughed away leaving a ragged cystic space. A small nodule of tumor was present on the anterior surface of the cervical cord. This nodule was solid and golden yellow.

No involvement of the cerebellum by tumor was seen nor were there any changes in the cerebrum itself. A few minute hemorrhages were present in the cerebrum scattered in several areas. These were interpreted as secondary to encephalography. Microscopic examination showed that the tumor itself consisted of a mixture of small vascular

area secondary to encephalography. Unfortunately, the eyes were not examined at autopsy. It was felt that the cause of death was respiratory failure secondary to mechanical pressure changes associated with hemorrhages in the cervical cord and medullary tumor and epidural hemorrhage in the region of the craniotomy.

This interesting case presents the findings of a disseminated defect involving the blood vessels and epithelial structures. It is believed by many that the vascular lesions of this defect are not true neoplasms nor are the epithelial dysplasias truly neoplastic. The term hamartoma has been used to categorize the vascular and epithelial changes and in this use implies that these are malformations in which the various tissues of the part are present in improper distribution or proportion, often with prominent excess of one particular tissue. Thus, since blood vessels are present in great numbers within the central nervous system and in the eye, the occurrence of vascular channels in these areas does not imply a neoplastic change. Also, such lesions designated as hamartomas do not possess disproportionate powers of growth, and though growth may be apparent for a period of many years, it reaches an ultimate conclusion. Apparent continued growth may represent simply the reaction of trauma or, in the case of vascular lesions, thrombosis or hemorrhage with resultant degenerative and edematous changes. It seems from the examination of the central nervous system lesion in this patient that the symptoms of exacerbation may well have resulted from such a vascular accident. Evidence of old and recent hemorrhage and necrosis were present. The epithelial lesions in this patient seemed even more likely to be malformations than neoplastic changes.

Doctor Erdbrink \* Doctor Aronson is to be complimented for his skillful evaluation of this very interesting case.

Ophthalmologists like to refer to angiomas of the retina as von Hippel's disease, and to angiomas of the central nervous system as Lindau's disease. Thus, the particular association of retinal and cerebellar hemangiomas is referred to as Lindau von Hippel disease, this being a congenital mesodermal malformation having neoplastic traits occurring in neuroectodermal tissue, the retina and the central nervous system.

Von Hippel's disease is relatively rare. It may be bilateral, if unilateral, the left eye may be slightly more frequently affected. It appears most commonly in the third decade of life, and there is a definite familial incidence.

Clinically, angiomas may be extremely pleomorphic, but there are stages of early vascular dilation and angiomatous formation, then hemorrhages, exudation, cyst formation, retinal detachment, and the

spaces and somewhat more solid areas of closely packed endothelial type cells. Pigment laden macrophages were present in the tumor tissue and in addition recent hemorrhage older hemorrhage and necrosis were also evident. Other portions those representing the grayish translucent cysts seen grossly consisted of larger spaces lined by endothelial cells and containing a coagulum of protein like material. The cellular makeup of the tumor was such that its origin appeared to be hamartomatous rather than actually neoplastic that is no evidences of malignant or invasive growth could be seen and the individual cells were of uniform structure. No other significant microscopic changes were seen in the central nervous system. The anterior lobe of the pituitary gland however did show several small areas of acute ischemic focal necrosis. The cause of this necrosis was not apparent from the examinations performed.

Other findings of interest were present in the abdominal viscera. The pancreas showed fibrosis of its body and tail and there were several small cystic spaces the largest measuring approximately 1 cm in diameter within its substance. Microscopic examination showed that these were lined by cuboidal and occasionally mucus type epithelium and surrounded by fibrous connective tissue. The islets and acinar structures of the pancreas appeared undisturbed. There was slight inflammatory infiltration in the areas of fibrosis. Slightly yellowish turbid fluid was present in one of these cysts. Other cystic structures contained dark bloodstained fluid. No obstructive change in the pancreatic duct system was found.

Both kidneys contained several small smooth walled cysts filled with clear fluid. The largest of these measured approximately 7 mm in diameter. A disk shaped scar which extended deep into the substance of the organ was present in the right kidney and measured 7 mm in greatest dimension. Microscopic examination of this area showed that immediately adjacent to the scar a small localized collection of cells with clear cytoplasm containing fine vacuoles and small evenly stained nuclei was present. These cells resembled those of the adrenal cortex. This was the only focus of such tissue found in the kidneys. The renal cysts were lined by a flattened to cuboidal epithelium. No angiomatic lesions were found in the abdominal viscera. A few small areas of focal cortical hyperplasia of the left adrenal gland were present. The urinary bladder was congested and its mucosa edematous. However it contained clear urine. No other significant abnormalities were discovered at the autopsy examination.

Review of the pancreatic tissue previously removed at operation revealed a structure similar to that of the lesions present in the pancreas at autopsy. The anatomic diagnoses then were (1) hemangioma of the cervical spinal cord the medulla and the pons (2) Lindau von Hippel syndrome consisting of a central nervous system angioma with pancreatic cysts renal cysts adenoma of the right kidney and angioma of the left eye (3) epidural hemorrhage over the right occipital

Doctor Watts: A careful study<sup>7</sup> of the family history of a patient with this disease, by means of public records and written statements in family Bibles and covering a period of about nine generations, appeared in the *American Medical Association Journal* in recent months. It showed strikingly the familial and hereditary aspects, and also demonstrated the varied clinical manifestations.

We selected this case for presentation because it offered a consideration of an unusual and interesting disease. So far as practical implications are concerned, the participants have mentioned that while complete therapeutic success is unusual, definite benefit to the patient in the form of symptomatic relief may be obtained. An awareness of the nature of these lesions and of their hereditary occurrence may prove helpful in the detection and management of some of these patients.

#### Pathologic diagnoses

- 1 Hemangioma of the cervical spinal cord, the medulla, and the pons
- 2 Lindau von Hippel syndrome consisting of central nervous system angioma with pinneric cysts, renal cysts, and noma of the right kidney, and angioma of the left eye
- 3 Epidural hemorrhage over the right occipital region, secondary to oncophalography

final stage of glaucoma and ultimate functional destruction of the eye. Ophthalmoscopically the typical stage of the disease exhibits a cystic tumor in the peripheral retina with greatly dilated vessels running out to feed it. The course of the disease is relatively slow but the progression is relentless.

Therapeutic efforts in angiomatosis retinae consist of electro-surgery and x ray radiation. The prognosis is poor unless the disease process is treated extremely early in its course.

Doctor Watts: Does any retinal angioma mean von Hippel's disease?

Doctor Erdbrink: No. Congenital tortuosity and dilatation of the retinal vessels, an arteriovenous aneurysm of the retinal vessels, a circumscribed capillary hemangioma of the retina, and Coats's disease (massive exudative and hemorrhagic retinitis) must be considered in the differential diagnosis. A cavernous hemangioma of the optic disk should not be confusing, nor should the choroidal angioma of the Sturge-Weber syndrome.

Doctor Aronson: In my experience it is unusual to see angiomatosis retinae with angioma of the nervous system. That is most cases of central nervous system angiomas do not show retinal angiomas.

Doctor Romanul: I should like to differ with Doctor Aronson. I have seen several patients with central nervous system hemangioma in whom no retinal lesion was seen before operation. After operation, however, when the diagnosis had been established, careful funduscopic study showed peripherally located hemangiomatous lesions. I believe that due to the unfortunate habit of most neurologists and neurosurgeons to limit their funduscopic examination to the disk and sometimes also the macula, many peripherally situated hemangiomas are not seen. It is difficult therefore to estimate the incidence of retinal lesions in any particular series.

Doctor Aronson: My experience and the literature show a rare association of the two lesions. Perhaps many of the reported cases were examined only by neurologists and neurosurgeons and without the use of a cycloplegic agent. This would account for missing some of the less conspicuous peripheral lesions. I am sure that a competent ophthalmologist can see many things a neurologist might overlook.

Doctor Turville: What does surgery offer in these cases?

Doctor Aronson: Decompression procedures may give long relief. These are not malignant lesions. The patient under discussion here would have done better with earlier decompression.

Doctor Cooper:

Are there any x rays on this case?

By and large the psychotic population, as I encountered sample of it, is being managed in an inefficient fashion. The physical facilities of the various hospitals provide inadequate closed ward accommodations. I was impressed by the measures taken to provide security for these patients. Their design, for the most part, has been improvised from existing physical facilities, employing local material and labor. In the face of this somewhat restricted choice, the responsible medical officers had to house their psychotic patients in physical settings which, if anything, tend to overemphasize the physical security aspects. Window guards, furniture, and doors tend to resemble maximum security installations such as prisons, and hence are somewhat depressing. It should be emphasized that this has not been by planned design, and the psychiatrists and the administrative medical officers are conscious of the inherent esthetic and therapeutic deficiencies. The point to be made is one for future planning, namely, that a therapeutic atmosphere is conducive to treatment. The patient and the staff both feel it and are encouraged by it. The converse is equally true.

Data have been accumulating lately which tend to show substantially that there are very potent therapeutic forces active in the physical and social situation of a mental hospital ward. Those lead to therapeutic advantage or disadvantage dependent upon their recognition by the responsible medical group. Acting out in the form of assaultive, destructive behavior or suicidal attempts or gestures or escape maneuvers may be encouraged or discouraged by the implications of the prevailing attitude. In those institutions where trust and respect of psychotic patients is explicit in the physical structure as well as the demeanor of the attending personnel, there is a gratifying low incidence of the disturbance colloquially thought to be characteristic of the insane. Obviously the Army hospitals which I saw were limited in this regard.

It has been contended with what appears to be irrefutable logic that unless there is a relatively immediate prospect of restoring a soldier to some kind of duty status, his definitive medical care and ultimate rehabilitation is the job and responsibility of the Veterans Administration. This policy is a clear, simple, and sensible one based on the thesis of division of medical responsibility among various governmental agencies so charged. The military establishment has a vital duty which should not be jeopardized by encumbering its facilities and personnel with obligations which can be discharged by other divisions of the Federal Government. Admittedly, it is a difficult task to draw a sharp line of distinction between the medical obligations which are properly the military's and those which are civilian agencies', however, since this becomes important only after the patient has left a theater of operations such as Europe, it is beyond the purview of this report.

## SERVICE ARTICLE

# PSYCHIATRIC PROBLEMS IN U S ARMY INSTALLATIONS IN EUROPE

HOWARD P. ROME, M.D.

THE military psychiatrist's job in a very important measure is concerned with dispositional activities. However, a psychiatrist's training conditions him to think almost automatically in terms of the best interests of the patient. These are often in contrast to the needs of a military organization whose standards are those of readiness for combat. There inevitably results from this discrepancy of goals conflict as to procedure despite directives regulations and the rest. It is incumbent upon a Psychiatrist Consultant to reconcile these disparate aims by frequent discussions and consultation. The problem is of sufficient magnitude to make such a task a full time job.

The reports of Civilian Psychiatric Consultants which I have been privileged to review have surveyed all of the roles of the psychiatrist medical officer as well as the kinds of problems with which he is confronted. There is little which I can add to them but it occurs to me that many of them are expressions of situations which can be understood best if they are couched in the sociologic context in which they occur.

## THE PROBLEM OF THE PSYCHOSES

There is a fixed incidence of frank psychoses which occurs in our military population. For example, 22 to 25 per thousand troops per annum. It is very unlikely that the benefits gained from even excellent mental hygiene programs will change this annual rate of psychoses despite the unquestioned benefit which accrues from them in other spheres. Granted that preliminary screens tend to filter out the overt psychoses, it follows that a rather remarkably fixed annual rate of these problems will require appropriate diagnosis, management and disposition. The facilities necessary for their adequate handling can be predicted from existing demographic data. Detection and separation through medical channels is the standard operating procedure.

Extracted from a report to the Surgeon General U.S. Army, 1st of the  
Army Medical Institute in Europe, made in September 1954.  
Doctor Rome at the Mayo Clinic, Rochester, Minn. He is a Consultant  
Surgeon General Department of the Army in Psychiatry and Neurology.

make up unfits him for military service except in certain extremely protected situations continues to baffle many. The basic nature of this problem eludes many of the less experienced psychiatrists. By the same token, company commanders fail to recognize these persons for what they are and the result is a virtual shuttle of the patient from duty to the hospital and back, with all that that implies. It is significant that in those installations staffed by the more experienced medical officers, who naturally establish a working liaison with the line officers whose troops they serve, this problem is negligible.

### PSYCHIATRIC HOSPITALIZATION VERSUS OPD MANAGEMENT

It was gratifying to see that on the whole considerable care is exercised in selecting patients for admission to the psychiatric wards. This shows not only a high degree of psychiatric therapeutic sophistication but also indicates a noteworthy educational achievement. The concept that psychiatric illness is an expression of a decompensation in the adaptive resources of a patient is one which takes many factors into consideration. Further, it emphasizes the functional, dynamic aspects leading to the symptomatic state in contrast to the older static idea which tended to overstress the immediate, current, descriptive expressions of disease in a sense analogous to organic disease. Fitness for duty in this enlightened concept of psychiatric function can be seen as a relative phenomenon, a composite of the resources and potentialities of the patient and the stressful circumstances of the situation in which he finds himself.

It was my impression that there is a prevailing tendency among the psychiatrists in this theater of operations to be less bound by descriptive, nosologic labels which heretofore have carried with them dispositional edict qualities. One gains the impression that on the whole there is a concerted effort to keep patients referred for consultation and possible psychiatric hospitalization on an active duty status if it is at all feasible. Along with this, there is considerable interest on the part of these medical officers to reinforce this decision with provisions for continuing outpatient psychotherapy. Supplemental to this, they feel encouraged to use the ancillary resources at their disposal to accomplish these desirable objectives: consultation with company commanders, suggestions as to duty assignments, and use of chaplain and social service facilities. The encouragement of this is strongly recommended. As a corollary, the creation of some standard on which suitability for treatment may be based is also recommended. This would enable the medical officer to spend that time available for outpatient department psychotherapy more equitably from the point of view of its potential worth to the Army.

In theaters of operation such as Europe, the hospitals of necessity have to have provisions for the care and treatment of the psychotic. The creation of a neuropsychiatric center as an area clearing house such as the one at Landstuhl streamlines the handling of those patients who for the most part cannot be returned to duty.

The criterion for disposition or return to duty should be based on an estimation of the immediate future effectiveness of the patient as a soldier, and not upon the established psychiatric diagnosis alone. It is well documented that a significant percentage of patients with frank psychoses can be returned to an effective status provided the complex organization of various services required for this are integrated appropriately.

There are additional compelling reasons which recommend this policy.

1 The concept that a diagnosis of psychosis per se is synonymous with separation from the service is extravagant both economically to the nation and medically to the individual. Unfortunately, this idea has prevailed for some time. It is based in part upon the attitude of hopelessness with which many persons view all psychiatric illness. Co-ordinated line and staff policies and actions and improved communication of these among the persons concerned can restore a number of these patients to effective duty.

2 A military medical establishment which concerns itself only with diagnosis and disposition tends to deteriorate professionally. It cannot attract and keep well trained competent physicians. Accordingly failing in this sphere its other medical and military services deteriorate commensurately.

3 Medical administrative policies other than this have a demoralizing influence upon military personnel in general for in efforts to rectify the individual instances of the injustice with which they are personally familiar there is created a spreading tendency to circumvent regulations and directives conceived of as rigid and unrealistic by individualized interpretation which tends in turn to make a travesty of policy in general.

4 The most effective policy is one that defines and sets relatively broad limits and allows for the executor of it to use his discretion and judgment. Its emphasis is permissive rather than prohibitive. This ensures full participation and grants authority as well as responsibility.

#### SEPARATION PROCEDURES

The authority for the administrative separation of unfit personnel is clearly defined by pertinent Army regulations. The problem of the so-called pseudoneurotic schizophrenic whose characterologic

make up unfits him for military service except in certain extremely protected situations continues to baffle many. The basic nature of this problem eludes many of the less experienced psychiatrists. ## MORALE

The morale of the military forces as reflected in the sample of medical officers whom I met requires discussion. It is not an easy job to assess the morale of any organization, much less one the size and complexity of the United States Army. There always is a tendency to reductionism and oversimplification which ascribes more importance to a few obvious elements than they deserve.

Hanson W. Baldwin, the military affairs analyst for the *New York Times*, recently observed that the morale of the military forces was at "its lowest point in the 25 years" of his firsthand knowledge of it as a reporter. His discussion went on to include a number of the factors which I also noted in my brief and limited contact. It is significant that at the relatively high level of medical officers, one senses the same things which Baldwin indicated are true for the entire military establishment. While certain problems are peculiar to medical officers, it is also true that they too are influenced by the same set of sociologic forces which operate on the Army as a whole.

First, it is evident that—as Baldwin also points out—one must distinguish between the hard core of regular Army and the larger reserve component which finds itself in uniform for a limited time. While not the most paramount, the economic factor is certainly important. This is particularly true of regular officers in the grades of Major, Lieutenant Colonel, and Colonel. The material rewards of a professional life in the service are distinctly below what these men are entitled to, deserve, and could earn as civilians. While they are expected and indeed required to live on a social scale commensurate with their rank, they are not given the wherewithal with which to maintain this, educate their families, entertain as they deem it fit and are required to, and provide insurance for their families. This is made the more intolerable by the disparity which exists between them and their civilian colleagues in positions of comparable authority and responsibility. Then also the perquisites have been whittled down progressively.

The policy has been to create incentives for the lower ranked officers, and while this in itself is fine, unless similarly scaled advantages exist for officers who elect this as a permanent career, the country will be faced with a dearth of trained, experienced, higher echelon leaders. Resignations from the service by higher ranked officers is too high at present, as is generally recognized, however, the reasons for this are not fully appreciated. Medical officers in particular now have available to them civilian positions with emoluments far beyond those which they can hope to achieve by remaining permanently in military service. The effect of this upon their wives and families has to be reckoned with, for therein lies a major source of potential dissatisfaction.

The net result of this activity has been that the census on the inpatient hospital services in most installations is at a minimum. Those patients who are admitted are there for evaluative studies or because a trial of duty has shown conclusively their medical unfitness or because of complicating factors that clearly warrant hospitalization.

I found few installations with statistical data which truly reflect the large amount of this kind of work being done unless the patient is formally admitted to the hospital. He does not appear on the daily records as a patient. Obviously efforts in this direction are very rewarding. They result in a much higher quality of psychiatric care and service than is officially evident in regular hospital reports. A more accurate appraisal of work actually done would be had from some inclusion of these data in the regular forms that are officially submitted.

Then too it must be evident that this function employs psychiatrists at their most efficient level. Their professional acumen and therapeutic skill is enhanced commensurately at the same time that the patients and their units benefit from the use of even partial services. In a peacetime military establishment particularly this procedure has much to recommend it.

#### PSYCHIATRIC MEDICAL OFFICERS

The large majority of medical officers assigned to the psychiatric services of the installations I visited had had some graduate training in psychiatry before entering on this tour of duty. The Chiefs of the services of the larger hospitals are board certified or eligible by virtue of specialized training they have received. Those officers with more junior status expressed keen interest in ultimately qualifying for specialty certification. This as I see it attests a degree of motivation which can only reflect beneficially upon their patients. Accordingly staff conferences and more or less formal reviews of current literature as well as the actual collection and recording of psychiatric data are entered into in a highly satisfactory manner. The conferences I was privileged to attend were the equal of any I have witnessed in the better civilian teaching institutions.

Within the limitations of time and resources permitted by the fact that they are in the Army it was my feeling that the quality of individual patient care being given was of a high order. However with almost no exception these very capable young officers all plan to leave the Army at the conclusion of their obligated period of service. Also it can be anticipated that in the future the level of preliminary training by officers assuming these responsibilities will be lower than those now serving and hence their skill proportionately less.

young male adults who are not engaged in actual combat with an enemy, but also their dependents—wives and young children. Consequently, the burden imposed by the medical care of these dependents has to be reckoned with. As is true of women in the most fertile time of their childbearing, in only marriage and when they are relatively young, there are a host of medical, obstetric, gynecologic, and psychiatric problems that occur among them. I have no information which would lead to the conclusion that these are disproportionate. By the same token, however, the whole complex of pediatric and developmental problems of dependent children is also the Medical Service's responsibility.

While I am sure that these are self-evident facts, I have the impression that for reasons not within the control of the Medical Service they tend to be subordinated in importance. The medical officer in general is expected to wear three hats: the first, as a general practitioner with a burgeoning family medical practice, the second, as a field medical officer familiar with and capable of dealing with the problems of an army in the field, and the third, as a competent specialist in one or the other of the many specialized fields in medicine, who is expected to function as he would were he in a teaching hospital. While this summary statement obviously requires modifications and amendments to be wholly accurate, it suffices to point up some of the ramifications and complexities of the medical officer's job. Each facet demands progressively more, in order to more adequately and more completely do the job with which it is concerned. This takes time, training, and leadership, as well as people, and yet it is all couched within the framework of personnel ceilings, military strategy, domestic and foreign political implications, limited medical manpower resources, and financial restrictions.

The solution of the conflicts among these often conflicting demands is neither immediately apparent nor easy, but has to be sought after by everyone involved, this includes many civilian groups whose tendency it has been to divest themselves from responsibility and content themselves with special pleadings for special interests.

### CONCLUSIONS

It is manifest that any brief encounter such as mine with problems of the order of magnitude such as those confronting the Medical Service in its European theater is hardly sufficient on which to even entertain an opinion. My respect for the job being done and the people doing it has grown immeasurably as a consequence of this limited view of their operations. Further, this opportunity has made me more conscious of my obligations and responsibilities as a citizen, a physician, and a teacher.

While some recognition of this is indicated by the additional pay given to medical officers it is not enough. The factors of status and prestige have to be thought of. By tradition promotions in the Medical Service are geared to line requirements. It has been demonstrated in various states as well as civilian Federal agencies that trained medical personnel have to be paid salaries at a higher level than other civil service positions of comparable status if good medical service is to be had. For example, while the Governors of several midwestern states receive salaries averaging \$15 000 per year the subordinate position of Commissioner of Mental Health in their states carried with it a salary of from \$18 000 to \$20 000 per year. While it may be hoped that Congress will rectify the relatively low pay scale of the military efforts should also be made to free what seems to be an encumbered promotion policy.

Since World War II particularly the military establishment has recognized the rightful place of medical specialists. However in the higher ranks at a time when maximum returns may be expected from long term professional investments it is still necessary for highly trained medical officers to assume full time administrative responsibilities for which they may or may not be suited and especially trained if they are to remain in a favorable competitive position in the promotion scale. This seems to be a wasteful expedient. One outstanding consequence from a morale point of view is the rivalry created between those officers who have had specialty training and those who by election or necessity have chosen administrative careers.

The policies of various high level advisory groups also affect the job of the Medical Service as a whole as well as its individual officers. Medical staffing patterns seem to be based on troop strength while the demand for medical services is on the realistic basis of troops plus their dependents. In many instances the tax which this imposes is expressed in terms of widespread dissatisfaction by the physician as well as his patient both of whom feel victimized by "the system."

### THE MEDICAL OFFICER'S JOB

In its widest angle perspective an appreciation of the medical officer's job takes in a great deal far beyond the scope of the actual technical practice of medicine. As I saw it and as I am capable of judging it the actual quality of medical service being given patients is of a superior kind.

As I have mentioned previously the staffing ratios of assignments of medical officers to the theater is on the basis of total military strength. It happens however that these officers not only serve a reasonably well selected physically healthy group of

disordered liver function, such as increased prothrombin time and hyponalbuminemia, are not present (5) Specific pathologic changes of the liver are observed. Grossly, the liver is dark brown to black. The consistency may be firmer than normal. Microscopically, there is a coarsely granular brown pigment in the hepatic cells. This is most marked near the central vein and in the central two thirds of the lobule. There is pigment in the Kupffer cells in some cases. The nature of this pigment is unknown, but is reportedly similar to the lipochromes.<sup>11</sup> This entity was described independently in 1954 by Sprinz and Nelson.<sup>12</sup> Since then a number of reports of cases have appeared in the literature.<sup>13-15</sup> It is considered likely that this is a definite pathologic entity, probably different from constitutional hyperbilirubinemia.

We should like to report another case of Dubin Johnson syndrome, proved by liver biopsy and with a familial occurrence (by history).

### CASE REPORT

A 22 year old soldier was admitted to this hospital in November 1955 because of icterus, fatigue and nausea and vomiting of three to four days duration.

**Past History.** The patient stated that he had noticed yellow color in his eyes since the age of 12. This had waxed and waned repeatedly. At the age of 18 he suffered from malaise, nausea and vomiting and increase in his jaundice. A diagnosis of hepatitis was made. He improved gradually over a period of 3 to 4 months. At the age of 19 years shortly after entering college he was operated on for acute appendicitis. The surgeon told the patient that his tissues were yellow at operation. Postoperatively he developed deep jaundice. Liver tests were performed for the first time and a diagnosis of "recurrent hepatitis" was made. Convalescence again took 3 to 4 months. For the next two years the patient attempted working at several jobs and he once more entered college. Each endeavor was terminated because of weakness, fatigue and lack of energy.

He was drafted in June 1955 at the age of 22 years. He felt fairly well during basic training but shortly thereafter he once more became very fatigued and weak. He developed a "funny pulsating feeling" in the right upper quadrant, nausea, vomiting and increased icterus and was admitted to the hospital for study.

**Family History.** Family history revealed that the patient's father, age 47 years, had suffered from chronic jaundice and had been told that he had "chronic hepatitis." One sister, 23 years of age, also had "chronic hepatitis." Both were fatigued but were able to work regularly, (as

train brakeman and school teacher respectively) Another sister 18 years of age was normal

Physical Examination. The patient was a well-developed and well nourished young man His temperature was 99.4°F pulse rate 80 blood pressure 115/75 mm Hg and respirations 22 per minute The scleras were icteric the skin was not thought to be jaundiced Physical examination was otherwise entirely negative At no time was either the liver or spleen palpated

Laboratory Studies White blood cell count was 7 800 per  $\mu$ l with a differential of 59 polymorphonuclear leukocytes 28 per cent lymphocytes 8 per cent monocytes and 5 per cent eosinophils Hematocrit was 44 ml per 100 ml sedimentation rate 9 mm at the end of the first hour The direct bilirubin was 2.8 and the total bilirubin 4.0 mg per 100 ml The sulfobromophthalein sodium retention was between 8 and 15 per cent Cephalin cholesterol flocculation varied from 1 to 2 at 48 hours thymol turbidity from 1.5 to 4.4 units at 48 hours Bile was present in the urine and urine urobilinogen was 1.40 Prothrombin time was 100 per cent of normal Total protein was 6.5 grams per 100 ml with albumin globulin ratio of 3.6:2.8 Alkaline phosphatase was 4 units cholesterol was 283 mg per 100 ml with 70 per cent of the total as esters Reticulocyte count was less than 1 per cent of the erythrocyte count Coombs test was negative

Röntgenographic findings of the chest were negative Cholecystograms failed to demonstrate gallbladder filling

strong familial history of jaundice, the patient's story of recurrent icterus for several years, malaise, normal hemogram, and borderline normal liver function point strongly to the diagnosis of Dubin Johnson's syndrome or the separate entity known as constitutional hyperbilirubinemia. It is stressed that at present the two entities are thought to be distinct, both pathologically and clinically, the former having both an elevated total and direct serum bilirubin with the characteristic pigment in the liver. A review of the literature indicates that the hereditary factor is not nearly as evident in Dubin Johnson's syndrome as in constitutional hyperbilirubinemia.

In the differential diagnosis, subacute hepatitis or postnecrotic cirrhosis of chemical or viral cause should be considered. In these diseases an enlarged nodular liver and positive flocculation studies indicate a pathologic as well as functional change found in the liver. The liver is not significantly enlarged nor are the flocculation studies typically positive in the syndromes considered in this article.

The minimal jaundice, right upper quadrant discomfort, fever, and roentgenographic evidence of a poorly or nonfunctioning gall bladder may lead to the erroneous diagnosis of primary gall bladder or bile duct disease. The history and liver biopsy demonstrating the abnormal pigment would be diagnostic of hepatic dysfunction of the Dubin Johnson type. In constitutional hyperbilirubinemia, the gallbladder may be seen in the cholecystogram.

The hepatic dysfunction syndromes ordinarily should not be confused clinically with a hemolytic process of a hereditary or acquired type, because the hemogram, red blood cell fragility study, Coombs' test, and reticulocyte determinations are well within normal limits. Also, in hemolytic disease, the spleen is frequently palpable.

Needless to say, the cause of hepatic dysfunction of the Dubin Johnson type or of constitutional hyperbilirubinemia is unknown. A hereditary factor is probably important, particularly in the latter condition. The conditions seem to be more prevalent in men than in women. It is remarkable that the pigment peculiar to Dubin Johnson's syndrome has not been described at post mortem examination heretofore.<sup>13</sup>

No specific treatment is known at present. Cortisone has been tried in constitutional hyperbilirubinemia without success.<sup>14</sup> The rationale of this therapy was based on the fact that corticosteroids are known to decrease jaundice in acute viral hepatitis.

Prognosis in both types of hepatic dysfunction is considered to be good with respect to life expectancy. Certainly, the symp-

toms of a recurrent nature can limit an individual's activity at least temporarily and may impose permanent physical limitations. From the cases studied to date subsequent irreversible liver cell damage in later life has not been demonstrated.

## SUMMARY

The Dubin Johnson syndrome is believed to be a distinct disease entity in which there is hyperbilirubinemia manifested clinically as in form of chronic or intermittent jaundice. Histologically the disease is characterized by the presence of a coarsely granular brown pigment in the hepatic cells. The usual symptoms are abdominal pain, nausea and fatigue. Jaundice, dark urine and slight enlargement of the liver are usually present. The jaundice is aggravated by intercurrent illnesses and fluctuates in intensity. The prognosis is good.

The disease differs from constitutional bilirubinemia in that (1) the symptoms are more prominent (2) the liver is frequently palpable (3) bilirubinemia is more severe and the serum bilirubin gives primarily a direct van den Bergh reaction (4) bilirubinuria is more common (5) liver function tests such as sulfobromophthaloin sodium excretion cephalin cholesterol flocculation, and turbidity tests may be abnormal (6) the gallbladder may not be seen in a cholecystogram and (7) there are specific pathologic changes in the liver.

The diagnosis of Dubin-Johnson syndrome in the patient described in this report was proved by liver biopsy. History disclosed a familial occurrence.

At present the primary importance of this syndrome is that it be accurately differentiated from (1) chronic and subacute hepatitis in order that the patient may be assured of a good prognosis and from (2) obstructive jaundice in order that unnecessary surgical procedures may be prevented.

### HELPING THE DISTURBED

"The main characteristic of mental ill health is inability to bear experience. The condition which takes the distressed human being to the psychiatrist is fundamentally the same as that which takes him to the priest or to the philosopher and it is legitimate and important to compare what each has to offer to the disturbed mind.

"The psychiatrist today is equipped as doctors fifty years ago were not with techniques for uncovering the origin and nature of mental stress with theories to mitigate its unbearable quality and with drugs to blunt its physical effects. He is less well equipped with means physical or psychological for raising the threshold of what can be borne with impunity.

# Constitutional Hepatic Dysfunction

NICHOLAS H. ZELLER *Captain MC USA*  
GERD SCHLEEFE *MD*

THE icteric condition which today is recognized as constitutional hepatic dysfunction or familial nonhemolytic jaundice was first described by Gilbert and his associates<sup>1</sup> during the early 1900's, and called *cholemie simple familiale*. Pozendaal, Comfort, and Saell<sup>2</sup> in an analysis of cases of slight and latent jaundice included instances of familial nonhemolytic nonobstructive jaundice.

Subsequent reviews of the condition were published by Comfort<sup>3</sup> and Comfort and Hoyne<sup>4</sup> who delineated the criteria for diagnosis and included a clinical study of 35 cases. It was stressed that the jaundice is not due to disease of the blood, liver, or biliary tract, but apparently is caused by an abnormally high threshold for excretion of bilirubin formed at the usual rate. This was attributed to an inborn deficiency of the hepatic cells with respect to the excretion of bilirubin. Comfort proposed the term constitutional hepatic dysfunction as best indicating the nature of the condition and the organ involved. In 1941 Meulengracht<sup>5</sup> reported 35 cases of chronic intermittent jaundice which conformed to the entity under discussion.

The sole manifestation of the condition is jaundice, which may become apparent at any age and which may be intermittent or persistent. It is usually familial but cannot always be demonstrated to be so. When familial it is believed that the condition is inherited as a dominant Mendelian trait which may be carried by either sex.<sup>7</sup> It is not common but the exact incidence has not been determined. The elevated blood bilirubin is always indirect reacting. In 1941 Dameshek and Singer<sup>6</sup> reported a greatly delayed excretion of injected bilirubin during bilirubin excretion tests in two families with familial nonhemolytic jaundice.

Constitutional hepatic dysfunction apparently does not produce symptoms but it is usual for individuals with the condition to complain of neurasthenia and fatigability.<sup>1-3, 7</sup> Emotional stress has also been related to appearance or exacerbation of icterus in affected individuals.

---

From U. S. Army Hospital 8212, Berlin, Germany. Dr. Zeller is now at 1113 E. St. Cherokee, Springfield, Mo.

The diagnosis is usually one of exclusion. Initially, following the report of an elevated indirect reacting bilirubin, the patient is usually thought to have hemolytic disease. This can be excluded by history, a normal appearing bone marrow, an absence of anemia, reticulocytosis and splenomegaly, normal size, shape, and osmotic fragility of erythrocytes, a negative Coombs' test, a normal erythrocyte survival time, and a lack of increased excretion of fecal and urinary urobilinogen. A normal excretion of fecal urobilinogen may be the only means of distinguishing constitutional hepatic dysfunction from a mild hemolytic process without demonstrable anemia.

Hepatic disease is ruled out by history, absence of hepatic enlargement, normal hepatic architecture on histologic examination when liver biopsy is performed, and normal liver function studies (other than the bilirubin excretion test), including sulfobromophthalein sodium excretion test.

The jaundice of gallbladder disease and other intra or extra hepatic biliary obstruction is associated with an increase in the direct reacting bilirubin in the serum, and with other characteristic features of disease of the biliary tract.

A condition of nonhemolytic hypobilirubinemia associated with lipochrome like pigment in the liver cells has been reported.<sup>11</sup> In addition to the pigment deposits noted, the bilirubinemia is characterized by a relatively high direct reacting fraction, and a mild elevation of the sulfobromophthalein sodium retention.

Accurate diagnosis of constitutional hepatic dysfunction or familial nonhemolytic icterus is essential. An erroneous diagnosis of liver or biliary tract disease might lead to unnecessary exploratory surgery, prolonged period of hospitalization, data limitations, or even dismissal from the service, whereas a diagnosis of hemolytic disease may be followed by unnecessary and useless splenectomy.

The prognosis is excellent and life expectancy is not affected. No specific treatment is indicated. Explanation to the patient of the benign nature of the condition is often sufficient to remove many of his functional complaints.

### CASE REPORT

A 28 year-old white Puerto Rican was admitted to this hospital on 26 February 1956. He stated that he felt well until about five days prior to admission when he noticed onset of headache and a general weakness of his legs. He experienced chills, sensations and a "feeling" about two days before admission. He thought this was a

become darker in color about two days before entry but noticed no change in color of his stools. On the day before admission he was told his skin was yellow. He had no nausea, vomiting or abdominal pain. He had received a routine influenza inoculation in November 1955.

**Post History.** The patient was told in 1953 that he was jaundiced. He stated that his skin never cleared up although he never felt as bad as he did on admission. He had been under the care of a psychiatrist as an outpatient at his present duty station for treatment of a chronic anxiety neurosis, and since April 1955 had been receiving reserpine daily. A fellow member of the patient's service company had been hospitalized shortly after the patient's admission with a subsequently substantiated diagnosis of infectious hepatitis. The patient had been a worker in a watch crystal factory prior to entering the Army in 1951. He served in Korea during 1951-1952 and had been in his present command for about one year. He denied alcoholic intake or exposure to possible hepatotoxins or hemolytic agents; he denied any history of jaundice or liver trouble among members of his family. He is the second of eight siblings, all of whom are living and well.

**Physical Examination.** The patient was a fairly well-developed and nourished white male who did not appear ill. He was alert but tense and apprehensive. His temperature was 99°F, blood pressure 110/60 mm Hg, pulse rate 80 per minute. There were no abnormal physical findings other than moderate icterus of the scleras and skin. There was no enlargement of any abdominal organ. There were no stigmata of chronic liver disease. Digital rectal examination revealed a small amount of brown stool.

**Laboratory Studies.** The leukocyte and differential counts were normal. Hemoglobin was 14.3 grams per 100 ml, hematocrit 43 ml per 100 ml, corrected sedimentation rate 20 mm in 1 hour. Routine urinalyses were negative for sugar and albumin and negative microscopically. The microflocculation test for syphilis was negative. Serum amylase, fasting blood sugar, blood urea nitrogen, and prothrombin time were all within normal limits. The heterophile antibody titer was 1:14. Coombs test negative, reticulocyte count 1.5 per cent of erythrocyte count. Erythrocyte fragility studies showed beginning hemolysis at 0.44 per cent NaCl, complete hemolysis at 0.30 per cent NaCl; control beginning hemolysis at 0.42 per cent NaCl, complete hemolysis at 0.32 per cent NaCl. Total serum proteins were 7.5 grams per 100 ml with an albumin-globulin ratio of 5:1.2.4. Initial serum bilirubin 5.25 mg per 100 ml with an indirect or delayed component of 5.02 mg per 100 ml. Serum cholesterol 236 mg per 100 ml with an esterified fraction of 72 per cent. Alkaline phosphatase 2.2 Bodansky units, rhmol turbidity 2.3 units, cephalin-cholesterol flocculation negative at 48 hours. There was 2.5 per cent retention of sulfobromophthalein sodium 45 minutes after intravenous injection of 5 mg per kilogram of body weight. Urinary urobilinogen was 1 Ehrlich unit in a 2-hour afternoon specimen. Fecal urobilinogen excretion was 105 mg per 24 hours. Tests for

urinary porphobilinogen and uroporphyrin were negative. A bilirubin excretion test revealed 85 per cent retention 4 hours after injection of 50 mg of bilirubin intravenously, as compared with a normal retention of less than 5 per cent. Serial liver function studies during the period of hospitalization were always normal except for an elevation of the serum bilirubin which varied between 1.6 and 3.15 mg per 100 ml, the increase always being in the indirect fraction.

Roentgenographic findings of the chest were within normal limits and a cholecystogram revealed a normally functioning gallbladder.

**Course in Hospital.** The patient remained afebrile throughout the period of hospitalization. He was treated as for hepatitis until it was known that the laboratory studies were typical of constitutional hepatic dysfunction or familial nonhemolytic jaundice. Thereafter, he received no specific treatment and was returned to full duty on 27 March. Unfortunately, circumstances prevented any investigation into the possible occurrence of this condition among other members of the patient's family.

On 13 April the patient was readmitted to this hospital in an acute exacerbation of his chronic anxiety state. All laboratory studies were again within normal limits except for a slightly elevated serum bilirubin of 1.4 mg per 100 ml, with an indirect fraction of 1.25 mg per 100 ml. It is interesting to note that the serum bilirubin value was only slightly above the normal at a time when the symptoms of the patient's anxiety state were most prominent.

### SUMMARY

Constitutional hepatic dysfunction is a benign and relatively asymptomatic disease. The only manifestation of the condition is intermittent or persistent jaundice, which may become evident at any age. It apparently is caused by an abnormally high threshold in the hepatic cells for the excretion of bilirubin formed at the usual rate.

The only abnormal physical finding is the jaundice. Hyperbilirubinemia, from an elevated indirect reacting bilirubin, is the only abnormal laboratory finding. On histologic examination the liver tissue appears normal.

No specific treatment is indicated and the prognosis is excellent. Accurate diagnosis of constitutional hepatic dysfunction is essential to prevent unnecessary exploratory surgery or splenectomy, prolonged hospitalization, duty limitations, or even discharge from the service.

## HEPATIC COMA

"The relationship between ammonia intoxication and impending hepatic coma and even deep coma produced by protein and other nitrogenous substances such as ammonium chloride is by no means clear. It is true that some patients have a high venous blood level of ammonia when hepatic coma develops but the relation is not yet distinct nor constant enough to imply an etiological relationship. The empirical fact remains that in certain patients hepatic coma may be induced by protein whatever the biochemical defect may be."

—CHARLES S. DAVIDSON M.D.  
in *Journal of American Medical Association*, p. 391 Feb. 4, 1956

# Unique Renal Trauma

ANTHONY A BORSKI, Major MC USA

**T**HE traumatic severance of a renal artery which is presented here is unique in that no other major organs were involved and no ribs were fractured. Moreover, the kidney remained grossly intact during the trauma to its pedicle. Search of the literature failed to reveal a similar case. Previously reported cases of lacerated renal vessels had other organs involved and ended fatally. In the present case the severed renal artery was not diagnosed preoperatively.

## CASE REPORT

An 18 year old soldier was admitted to this hospital at 0900 hours on 1 February 1955 complaining of pain in the left flank and left side of his chest. The patient stated that he had jumped from a slow moving truck, slipped and fallen under the vehicle. His screams caused the driver to apply the brakes; however, the forward momentum of the truck pushed him several feet along the snow covered road as the rear wheels compressed the left side of his body. No treatment was received prior to admission to this hospital.

Physical examination revealed a well-developed and ambulatory patient. His blood pressure was 124/74 mm Hg, pulse 80, respiration 20, temperature 98.2°F. The thorax was symmetrical and well developed. There were several superficial abrasions over the left lateral thorax. The abdomen was soft and slightly tender in the left upper quadrant. There were no palpable masses. Peristalsis was normal. There was moderate tenderness and questionable bulging in the left flank. A few superficial abrasions were noted over the left flank. No other abnormalities were noted on physical examination.

A roentgenogram of the chest did not reveal evidence of any fractured ribs. The lungs were clear except for the left base where there were some signs of pneumonitis. There was no free air under the diaphragm.

A white blood cell count showed a total of 15,600 cells per  $\mu$ l with a differential count of 85 per cent neutrophils, 11 per cent lymphocytes and 4 per cent eosinophils. Red blood cell count was 4,500,000 per  $\mu$ l, hemoglobin 14 grams per 100 ml, and hematocrit 44 ml per 100 ml. Urine was normal.

---

From 121st Evacuation Hospital, Korea. Maj. Borski is now assigned to Fitzsimons Army Hospital, Denver, Colo.

The patient was admitted to the surgical service for observation for possible splenic injury. Approximately 10 hours following admission his blood pressure started to rise and 12 hours following admission it was 210/105 mm Hg and his pulse was 120. He had emesis and diaphoresis and the tenderness and bulging increased in the left flank. A urologist was consulted. His findings were essentially as already described but the flank mass was interpreted as due to renal injury and therefore an intravenous urogram was taken (fig 1). There was no apparent renal function on the left and the psoas outline was absent on the left. The bladder appeared normal on cystoscopy and clear urine

Figure 1 Intravenous urogram showing normal renal function on the right. Contrast media and renal outline are not visible on the left.

was spurting from the right ureteral orifice but there was no efflux from the left. A ureteral catheter was passed to the left renal pelvis but no urine was obtained. A left retrograde urogram revealed a normal left calyceal outline (fig 2).

We were therefore confronted with a patient who had a nonfunctioning left kidney with a normal calyceal outline. The kidney was de-

pressed and the psoas muscle outline was obliterated. There was marked bulging of the left flank which was interpreted as due to hemorrhage. Surgical intervention was undertaken using a transthoracic approach. When the diaphragm was incised a large collection of blood was noted. Approximately 1500 ml of blood was evacuated. The kidney appeared grossly normal and the capsule was intact but there was no pulsation at the pedicle. Examination of this region showed a 4 cm segment of a large vessel with a ragged end attached to the kidney. There was but one intact vessel to the kidney namely the vein. The surgeon confronted with a severed renal artery quickly clamped and

*Figure 2 Retrograde urogram showing a normal left calyceal outline. Residual contrast media from intravenous urogram faintly outlines the right kidney.*

divided the ureter and vein and removed the kidney. There was a very small segment of renal artery attached to the aorta which was clamped and ligated. The peritoneal cavity was explored and the spleen and intestines were found to be intact.

Blood pressure returned to normal levels on the third postoperative day. The postoperative course was uneventful except for a small co

lection of pleural fluid which was aspirated on the fourteenth post operative day. A roentgenogram of the chest taken one month after discharge from the hospital revealed normal findings and the patient was asymptomatic.

### DISCUSSION

This case presented several puzzling aspects. Initially splenic or renal injury was suspected. The presence of intact ribs, normal urinalysis, blood studies, and vital signs, and the absence of a definite mass in the left flank contributed to a later impression of contusion of the thorax and left flank. The benign symptoms and normal laboratory findings led the physician to omit obtaining on admission an abdominal roentgenogram of the kidneys, ureters, and bladder (KUB) and an intravenous urogram. Ten hours following admission the patient apparently had considerable hemorrhage as evidenced by the physical and operative findings.

Preoperatively we interpreted the hypertension as most likely due to adrenal damage and the depression of the kidney by the suprarenal mass (blood). The source of the blood was believed due to a laceration of the renal cortex without injury to the calyces or pelvis. The cause of the nonfunctioning kidney was known but reflex anuria secondary to renal trauma or obstruction of the renal vein or artery by an embolus were possibilities. Displacement of the kidney in such a manner as to cause compression of the pedicle would have produced an abnormal retrograde urogram. Aortography was not feasible because of the flank mass. The transthoracic approach was used for better exposure and also to fully evaluate the spleen and abdominal viscera. In retrospect it is believed that the proximal segment of the renal artery went into vasospasm immediately after the severance of the artery and it was only after a delay of about 10 hours that secondary hemorrhage occurred. It is amazing that the compressing force of the injury could selectively cause severance of the renal artery without rupture or distortion of the renal parenchyma.

# Homozygous Hemoglobin C Disease

## Relation to Military Service

ROBERT D GENS *Captain, USAF (MC)*

**S**INCE the demonstration by Pauling and associates<sup>1</sup> that normal human hemoglobin and sickle cell hemoglobin differ in electrophoretic mobility, it has been possible by the use of electrophoresis to identify a series of abnormal human hemoglobins. Research in this area was at first slow, because electrophoretic identification of abnormal hemoglobins was made with the cumbersome and costly Tiselius apparatus. Recently, however, the development of filter paper electrophoresis has permitted the rapid and inexpensive identification of a patient's hemoglobin type, with the result that in many laboratories, including our own, electrophoretic identification of a patient's hemoglobin type is a routine procedure when studying a patient for a suspected hereditary anemia.

The purpose of this article is to discuss the signs, symptoms, and laboratory findings of a patient with homozygous hemoglobin C disease and to relate these findings to the patient's service desirability.

### CASE REPORT

A 22 year old Negro airman was recently admitted to our hospital with a laceration of his right thigh. He denied any history of jaundice, fatigability, joint or bone pain, or leg ulcers, and there was no family history of these abnormalities.

Physical examination revealed a well nourished, well developed man with no evidence of pallor or jaundice. His fingers were of normal size, and there was no evidence of leg ulcers. The spleen was firm with a sharp edge that was palpable 12 cm below the left costal margin. The liver was not palpable. The remainder of the physical examination was noncontributory.

Laboratory studies showed that hemoglobin was 10.5 g/100 ml, hematocrit 29 ml/100 ml, erythrocyte count 3,540,000/ $\mu$ l, with 12 percent reticulocytes, direct antiglobulin test negative, sickle cell prepa-

---

From U S Air Force Hospital, Eglin Air Force Base, Fla.

ration negative total serum bilirubin 0.8 mg/100 ml. A peripheral blood smear showed marked anisocytosis and poikilocytosis with some polychromatophilia approximately one half of the erythrocytes were target cells and an occasional spherocyte was present. 2.2 per cent of the hemoglobin was alkali resistant (the upper limit of normal for our laboratory). Osmotic fragility<sup>2</sup> showed a marked increase in resistance of the erythrocytes to hypotonic saline solution. Roentgenograms of the skull and chest showed no abnormalities.

The filter paper electrophoretic pattern (using the method of Smith and Conley<sup>3</sup>) is shown in figure 1. All of the patient's hemoglobin is

	Hemoglobin type		
	C	S	A
Standard	C A		
Standard	C S		
Patient	C C		
Wf	A A		
Child	C A		
Cord blood	F A		

Figure 1. Paper electrophoresis. Hemoglobin C migrates the slowest and hemoglobin A (normal) the fastest with hemoglobin S (sickle cell) intermediate in speed of migration.

seen to reside in the C fraction while his wife is homozygous for hemoglobin A. Their child is of course heterozygous for hemoglobins C and A.

### DISCUSSION

Hemoglobin C was first described by Itano and Neel.<sup>4</sup> It is transmitted genetically as a simple Mendelian dominant and has been estimated to occur in about three per cent of the Negro race. The occurrence of homozygous hemoglobin C disease in the American Negro is approximately 1 in 6,000.<sup>4</sup> A combination of hemoglobin C and hemoglobin A is clinically benign and is manifested by an altered electrophoretic pattern and leptocytosis (target cells). Neither anemia nor splenomegaly have been reported in this heterozygous state.

The patient's splenomegaly, mild anemia, increased erythrocyte production and leptocytosis are typical of homozygous hemoglobin C disease, in which the life span of the endogenous erythrocytes is known to be markedly diminished.<sup>7-9</sup> Although bone and joint pain symptoms are occasionally described,<sup>9</sup> there are no reports of abdominal pain, hemolytic crises, or splenic infarction in patients with this disease. Characteristically, they experience little distress while pursuing sedentary occupations.

This patient's spherocytosis is in accord with previously noted findings in homozygous hemoglobin C disease.<sup>10</sup> We believe the spherocytosis may be related to his splenomegaly, perhaps indicating "hypersplenism."

At present the patient is associated with a food service squadron, but we believe that a more rigorous life might produce clinical symptoms of anemia. Furthermore, splenomegaly predisposes him to splenic rupture via mechanical trauma. This factor might indicate the need for splenectomy, although splenectomy would not, of course, ameliorate the genetically determined hemolytic process. Discharge from the service should be seriously considered.

The literature concerning splenic rupture and hypoxemia<sup>11,12</sup> is pertinent to this airman, and our experience with him in an altitude chamber will be reported elsewhere.

### SUMMARY

A case of homozygous hemoglobin C disease is reported, and the possible military disposition of the patient is discussed.

---

ACKNOWLEDGMENT I am indebted to Dr. Barkley Beidleman, 1750 N. Palafox St., Pensacola, Fla., for the electrophoretic study.

# Meconium Ileus

## With Cystic Pancreatic Fibrosis and Early Pulmonary Complications

MELVIN E JENKINS *Captain USAF (MC)*

EVAN W SCHEAR *Major USAF (MC)*

**F**OR FOUR months we have had under observation a female infant who has manifested cystic fibrosis of the pancreas since birth. A successful operation for complete intestinal obstruction due to meconium ileus was performed at 23 hours of age. Her subsequent development, at six weeks of age, of the most typical early respiratory complication of this disease, lobar atelectasis, prompted this report.

### CASE REPORT

A full term white female newborn infant was delivered uneventfully on 13 March 1956 although some difficulty had been anticipated because of a rapidly progressing polyhydramnios in the mother, a 39 year-old multipara. There was no family history of congenital anomalies. Two half siblings had shown no evidence of cystic fibrosis of the pancreas.

After delivery induced by Pitocin (brand of oxytocin) the infant became moderately cyanotic and somewhat lethargic. An occasional cry was weak and "cephalic like." The abdomen seemed large. Birth weight was six pounds two and one half ounces. The circumference of the head was 14 inches, of the chest 11¼ inches, and of the abdomen 14 inches. The head appeared unusually large for so small an infant; however, no bulging or even tenseness of the anterior fontanelle was noted. The lung fields were relatively clear to auscultation and no cardiac murmurs were elicited. The abdomen, despite being obviously distended, was soft and exhibited a peculiar doughy sensation on palpation. No neurologic findings were apparent excepting moderate muscular weakness.

A nasal catheter was passed to the stomach without difficulty and a thermometer was inserted rectally. Roentgenograms of the abdomen at two and three fourths hours of age revealed a small air bubble in the stomach with no gas shadows distal to the pylorus.

---

From 6110th U S Air Force Hospital APO 710 San Francisco Calif

The red blood cell count was 5 470 000/ $\mu$ l and hemoglobin was 17.9 g/100 ml

The infant was watched closely for the next 18 hours during which time no meconium was passed and the abdominal distention increased. However, there was no vomiting of mucus or detectable drooling. Her general condition remained only fair with mild cyanosis of the hands and feet and moderate weakness. Repeat roentgenograms at 19 hours of age (fig. 1) revealed a complete lower bowel obstruction, making immediate operation mandatory. Surgical exploration of the abdomen at 23 hours of age revealed meconium ileus. Viscid meconium was present throughout the small intestine from the mid jejunum to within one inch of the cecum, the colon appearing cordlike. Since the process seemed to involve so lengthy a segment of small bowel, resection was deemed impractical.

Figure 1 Roentgenogram of abdomen at 19 hours of age demonstrating dilated duodenum and jejunum. No large bowel shadows are seen.

Enough of the meconium to relieve obstruction was removed with considerable difficulty through six enterotomy incisions, and a concentrated suspension of pancreatin was instilled during closure of the jejunum and ileum. The infant tolerated the lengthy procedure well. During the first 52 postoperative hours, continuous gastric suction was applied, and she was maintained on whole blood plus parenteral fluids and vitamins. Prophylactic antibiotics consisted of

60 mg (100 000 units) of aqueous sodium penicillin G given every eight hours and 100 mg of streptomycin sulfate given intramuscularly every 12 hours

On the third postoperative day a thin plug of whitish gray meconium was passed rectally after which moderate amounts of dark meconium followed at the rate of four to five stools per day. Gastric suction was discontinued on the third postoperative day and small amounts of glucose in water by mouth begun within eight hours of the start of glucose feedings. 5 ml of a weak Olac formula was accepted and tolerated well. The formula was continued every two hours and increased to 15 ml per feeding within 24 hours. 0.3 gram of pancreatic extract twice daily was given in the formula.

The infant's progress was steadily uphill after feedings were initiated. She quickly became much stronger and exhibited no adverse findings. She was discharged on the 15th postoperative day, to be followed weekly in view of the possibility of cystic fibrosis of the pancreas. For the first two weeks following her discharge from the hospital the patient seemed to progress well in weight gain, appetite and general appearance. A dry hacking cough with some wheezing developed at four weeks of age. At this time the infant was placed on a regimen of 50 mg of Terramycin (brand of oxytetracycline) every six hours and an expectorant cough mixture. Her formula was still being supplemented with vitamins and pancreatin. After improvement of the initial upper respiratory infection pancreatin was stopped and daily examination of stools for trypsin showed an absence of this enzyme.

At the age of six weeks the infant developed an episode of marked respiratory difficulty with what was described by the mother as a bluish discoloration of the skin. Physical examination at this time revealed an acutely ill infant who appeared in marked respiratory distress with obvious cyanosis and dehydration. There were crepitation and harsh rales throughout both lung fields with dullness to percussion over the right side of the chest. There was moderate subcostal retraction on inspiration. Roentgenograms revealed a pneumonic infiltration of the upper right lobe with evidence of segmental or lobar atelectasis (fig. 2). The infant was hospitalized and placed in an oxygen tent during the first week, taking nourishment poorly and requiring fluids intravenously. Antibiotic therapy consisted of 148.7 mg (150 000 units) of procaine penicillin G twice daily for 10 days and 100 mg of streptomycin sulfate every 12 hours for 12 days.

After the eighth hospital day gradual clinical improvement began. A follow up roentgenogram on the ninth hospital day revealed complete clearing of the pneumonic and atelectatic processes.

Follow up examination at four months of age revealed the infant to be progressing satisfactorily. She was on 50 mg of prophylactic

Terramycin twice daily. Her diet consisted of a full strength Olac formula, rice, cereal, bananas, strained meats, and a few strained fruits. She was taking multivitamin<sup>®</sup> in about four times the recommended daily dosage, and 0.2 gram of ferrous sulfate daily. Pancreatin was being continued (0.5 gram twice daily). At six months of age the patient was progressing fairly well in California, the family having returned to that state. However, pulmonary problems requiring medical care were evident.

*Figure 2. Roentgenogram of chest at six weeks of age revealing an opacity in the upper right lung field with narrowing of rib interspaces.*

#### DISCUSSION

The case presented above demonstrates the earliest manifestation of cystic fibrosis of the pancreas, meconium ileus. The symptoms of meconium ileus are essentially the same as those of any other form of obstruction of the lower small intestine in the newly born infant.

It is interesting that the obstetrician noted an unusually enlarged abdomen in the infant at birth. Initial roentgenograms of the abdomen at three hours of age revealed a gas pattern in the stomach only, interpreted by the radiologist as representing some form of intestinal obstruction.

Despite a 2½ hour abdominal operation at 27 hours of age entailing repeated manipulations of the small bowel and its mesentery, the infant's response postoperatively was satisfactory. In view of the observations that a few patients pass the obstructing meconium plug spontaneously after two or three days, one might delay operation in those patients with one or more siblings who have likewise had manifestations of cystic fibrosis of the pancreas. However, it must be kept in mind that the longer operation for intestinal obstruction in the newborn period is delayed, the more poorly these procedures are tolerated in general.

The episode of pneumonia and lobar atelectasis at six weeks of age is not unusual. In fact, lobar atelectasis with obstructive emphysema occurs in about 10 per cent of patients with cystic fibrosis of the pancreas.<sup>2</sup> It usually appears in early infancy during the first episode of pulmonary involvement and typically affects one or more lobes of the right lung. The condition is quite serious and may be rapidly fatal. Bronchoscopy and bronchial aspiration through a tracheotomy tube are usually ineffective.<sup>2</sup> Successful treatment of lobar atelectasis in this disease depends upon the intensive use of antibiotics and adequate nursing care.

An early fatal termination is not inevitable in cystic fibrosis of the pancreas if adequate therapy, including a dietary regimen, is given, although the prognosis is still poor for those patients who develop respiratory infections in the first two or three months of life. A high caloric diet is recommended in view of the associated poor nutrition. Proteins are well tolerated, although poorly utilized. A high protein diet—10 to 12 grams per kilogram of body weight—is usually recommended for young infants. Fats should be given sparingly with the essential fatty acids being supplied by egg yolk or peanut butter. The carbohydrate intake should be high chiefly to furnish needed calories. Vitamins A and D as supplements are required in about four times the usual dosages. Pancreatin is probably not needed after adequate nutritional progress has been established.

As a rule, prophylactic chemotherapeutics and/or antibiotics decrease the frequency and severity of respiratory infections. The administration of Gantrisin (brand of sulfisoxazole) in one fourth to one half the therapeutic dose will usually prevent the occurrence or progress of pulmonary infections. Terramycin or aureomycin (chlortetracycline hydrochloride) may likewise be used prophylactically.

## SUMMARY

A case of an infant with cystic fibrosis of the pancreas with meconium ileus at birth has been presented. A successful operation at 23 hours of age was followed by a relatively mild post-operative course. The patient's sudden development of pneumonia with lobar atelectasis at six weeks of age responded well to antibiotic therapy.

The dietary and antibiotic management of this disease is briefly discussed.

## PREVENTION OF RECURRENCE OF PSORIASIS

An important tenet in the treatment of psoriasis which will help minimize the frequency of recurrences is to overtreat the involved areas. Continued topical treatment for four to six weeks after the apparent resolution of lesions will often prevent a recurrence in these locations. The frequency of recurrences at identical sites of former lesions combined with recent work by the French school of dermatology showing that psoriatic lesions are often present after apparent clinical healing has taken place implies that the clinical disappearance of the lesions is an inadequate guide for the discontinuance of therapy.

# Rupture of the Esophagus by Compressed Carbon Dioxide

R MAURICE HOOD *Commander MC USA*

**T**RAUMATIC perforation of the esophagus may be produced by numerous types of external agents. Most frequently, endoscopic procedures and ingested foreign bodies are direct etiologic mechanisms. Penetrating and blast injuries are relatively infrequent even in wartime.

A case of rupture of the cervical esophagus by compressed carbon dioxide is reported here. A review of the literature revealed only three previously reported ruptures caused in a similar manner. In 1909, Petren<sup>1</sup> reported a case of rupture of the midesophagus in a 27 year old man who accidentally discharged a compressed air hose into his mouth. The man died 27 hours after injury. Kerr, Sloan, and O'Brien<sup>2</sup> reported the case of a 3 year old child who bit an inflated manor tube, producing a blow out of the tube into his mouth. Rupture of the thoracic esophagus just above the diaphragm resulted in a left tension pneumothorax with extensive mediastinal and subcutaneous emphysema. The child recovered following drainage of the pleural space and gastrostomy. Borghero<sup>3</sup> reported a case of rupture of the thoracic esophagus by compressed methane gas discharged accidentally into the patient's mouth. Similarly caused injuries involving the rectum and sigmoid colon are well known, and it is surprising that esophageal injuries of this type are not more common.

The esophagus is a thin walled, hollow viscus having no serosal covering. It is susceptible to perforation by rather minimal degrees of trauma. Kinsella, Morse, and Hertzog,<sup>4</sup> in an experimental study using fresh human cadavers, showed that rupture of the esophagus occurred at intraluminal pressures of 1.9 to 6.3 pounds per square inch. From their study it was also shown that the area of the esophagus just above the diaphragm was prone to rupture most easily. However, many other factors such as the level of intrapleural pressure, linear tension of the esophagus, rapidity of distention, and age of the patient would render the intraluminal pressure of rupture a variable and not a constant factor.

## PREVENTION OF RECURRENCE OF PSORIASIS

An important tenet in the treatment of psoriasis which will help minimize the frequency of recurrences is to overtreat the involved areas. Continued topical treatment for four to six weeks after the apparent resolution of lesions will often prevent a recurrence in these locations. The frequency of recurrences at identical sites of former lesions combined with recent work by the French school of dermatology showing that psoriatic lesions are often present after apparent clinical healing has taken place implies that the clinical disappearance of the lesions is an inadequate guide for the discontinuance of therapy.

—LAWRENCE FRANK M D  
in *American Practitioner and Digest of Treatment* p 874. Nov. 1954.

Figure 1 Roentgenogram made following a swallow of lipidol which demonstrates interstitial emphysema, extracastation of the mediastinum outside of the esophagus, and slight deviation of the trachea toward the right.

performed. Following this an oral surgeon reduced the open fracture of the nasal bone, left maxilla and floor of the left orbit.

The patient's postoperative course was surprisingly smooth. Tracheostomy was abandoned on the fifth postoperative day. Feeding by gastrostomy was discontinued on the eighth day and oral feedings were resumed on the fifteenth. The salivary fistula closed spontaneously after 10 days. The drains were removed on the twelfth day. There was never any systemic or local evidence of infection. The patient was transferred to the eye ear nose and throat service for further reconstructive surgery of the eye and facial bone. Five months after injury there was no evidence of stricture of the esophagus.

#### SUMMARY AND CONCLUSION

Injuries of the esophagus are frequently and easily overlooked in the early phase and particularly so when the attention of the physician is drawn to other severe chest or neck injuries. A patient with rupture of the cervical esophagus by carbon dioxide from a fire extinguisher, the associated cutaneous emphysema and a chest wound within five hours of injury is a possible

## CASE REPORT

The patient a 22 year old man was engaged in loading carbon dioxide fire extinguishers into a truck when he accidentally depressed the release handle. The nozzle recoil caused the hose and nozzle to swing around violently striking the man in the face. The full force of the expanding gas was directed at his nose and mouth. The pressure produced can only be guessed at (The cylinder pressure in these extinguishers is normally from 700 to 800 pounds per square inch at 70 F). He was dazed but not rendered unconscious. When seen by the medical officer 10 minutes after injury he was bleeding profusely from the nose and mouth. The patient was given 15 mg of morphine sulfate, a nasal pack was inserted and he was transferred to the hospital.

When examined in the emergency ward the patient was found to have an open comminuted fracture of the nose with an extensive soft tissue bruise and laceration over the left maxillary area. He was admitted to the eye ear nose and throat service. Four hours after admission he began to complain of substernal pain radiating through to the back. An intern noted subcutaneous emphysema of the soft tissues of the neck more marked on the left and extending over the anterior chest wall. Consultation from the thoracic surgery department was requested and examination of the patient at that time revealed no evidence of pneumothorax. The subcutaneous emphysema although present was not extensive and was not progressing rapidly.

A roentgenogram of the chest showed mediastinal and cervical emphysema but no pneumothorax. After the patient swallowed lipiodol a roentgenogram of the cervical and thoracic esophagus showed extensive extravasation of the medium into the tissues of the neck at the level of the lower border of the thyroid cartilage (fig 1).

The patient was taken to the operating room immediately and under general anesthesia the pharynx and upper esophagus were examined. A laceration beginning at the level of the upper margin of the epiglottis was seen extending down the posterolateral wall of the pharynx and to a point 5 cm below the cricopharyngeus muscle. An endotracheal tube was inserted and the skin prepared and draped. A 3 inch incision was made along the anterior border of the left sternomastoid muscle. The left inferior thyroid artery was ligated and divided and the thyroid gland and trachea were retracted to the right. Extensive emphysema, tissue discoloration and copious amounts of thin exudate having a faintly foul odor were encountered. The esophagus and lower pharynx were exposed and the previously described laceration visualized. At the lower end of the rear a 2 by 2 by 0.5 cm piece of bone was re-covered. This evidently was from the facial area and had been swallowed. Because of extensive edema and necrosis of the tissues involved in the laceration no primary suture was attempted. Three Penrose drains were placed in the area of the laceration and the wound was packed open. Tracheostomy and gastrostomy were immediately

## A MESSAGE FROM THE A M A

This is the second part of a report on the results of a continuing opinion survey of physicians released from active military service. The first part of this report appeared in last month's issue of the *U S Armed Forces Medical Journal*. This summary is based on 2,191 returns received in 1955 of a total of 3,651 questionnaires that were mailed out by the Council on National Defense of the American Medical Association.

**Evaluation of Military Medical Training** The great majority of physicians filling out the questionnaire believed that all important features of medical military training had been satisfactorily covered. For the Air Force, 85 per cent were satisfied with the training, while 15 per cent were not satisfied, in the Army, 78 per cent were satisfied, and 22 per cent were not satisfied, in the Navy, 70 per cent were satisfied and 30 per cent were not. The basic orientation and indoctrination courses on military customs, administration, and regulations were most frequently listed as subjects in which too little training had been given.

**Physicians' Evaluation of Assignment** A large majority of the physicians (approximately 75 per cent of the three services) indicated that they were properly assigned. Also, the number of physicians who were satisfied with their assignments was greater than the number not satisfied (although the majority was less decisive in this second case). In the Air Force 80 per cent indicated they were properly assigned, while in the Army it was 76 per cent, and in the Navy 69 per cent. Less than 1 per cent in the three services failed to answer this question. As to being satisfied with the assignment, again, the Air Force had the highest response of 71 per cent, followed by the Army with 69 per cent and the Navy with 67 per cent.

**Physicians' Evaluation of Staffing Conditions** One of the questions requested an opinion as to staffing conditions of nurses, enlisted medical personnel, physicians, dentists, and others at those units where the physicians had served. The tabulation of this multiple answer question indicates that, in the Army, replies of overstaffing totaled 660, understaffing 985, and adequate staff

necrosis, edema and infection made direct repair impossible. Adequate drainage of the area through a cervical incision, tracheostomy and gastrostomy resulted in control of infection and closure of the salivary fistula within 10 days without permanent disability.

#### CURIOSITY

Curiosity is one of the most important attributes of the mind and is indispensable in any educational process. One sees it at work in the animal kingdom: in the fledgling bird's first attempt at flight from the nest; in a kitten's tentative exploration of an unknown object; in the inquisitive sniffing of a dog at almost any vertical object. Young children have this divine gift of curiosity to a marked degree. It is a tragedy that all too often it is discouraged by stupid pedagogy. Fortunately curiosity is so much a part of living and learning that it is never wholly lost and with proper education can be made to grow again and thrive.

—JOHN H GIBBON, Jr. M.D.  
in *Annals of Surgery*  
p. 322, Sept. 1955

group in each service believed that all domestic duties could have been performed by civilian medical personnel

**Physicians Who Would Voluntarily Remain In Service** In response to the question relative to military service beyond the obligated tour of duty, 923 physicians indicated they would not be willing to stay in military service for more than their two years of service under any circumstances. A total of 1,203 physicians indicated they would serve an additional period under certain conditions. As expected, total war led the list of "certain conditions" for all three services, followed by "increase in pay." Other conditions on this list were choice of stable location or duty assignment, opportunity to practice specialty, and promotion to higher rank.

## Aero Medical Association Meeting

The Twenty Eighth Annual Aero Medical Association Meeting will be held in Denver Colo 6 7 and 8 May 1957 at the Shirley Savoy Hotel. Doctor Jan H Tillisch Rochester Minn President of the Association will open the sessions at 9 00 a m on the first day, after which Doctor Alberto Hurtado will deliver the Louis H Bauer lecture. Of considerable interest is the outstanding scientific program to be presented as multiple symposiums on the various disciplines allied to aviation medicine.

Among the prominent speakers scheduled are Colonel John P Strapp USAF (MC) Captain Norman L Barr MC USN Doctor Ross A McFarland of Harvard School of Public Health and such noted leaders in the field of civilian aviation medicine as Doctor L G Lederer Washington D C and Doctor C I Barron of Burbank Calif.

Colonel Paul A Campbell USAF (MC) will conduct the symposium on space travel in which such celebrated workers as Doctor Hubertus Strughold Doctor Vernher von Braun and Doctor Heinz Haber will participate.

The Association's annual banquet will be held on the evening of 8 May when the Lysrer Longacre and Tuttle Awards will be made. Colonel Levi M Browning Surgeon of the U S Air Force Academy is the general chairman of the 1957 meeting.

ing 2 005 In the Navy overstaffing totaled 400 understaffing 429 and inadequate staffing 1 146 The Air Force tabulation revealed 459 replies of overstaffing 892 of understaffing and 1 324 of adequate staffing By groups, physician overstaffing led the list in all three services followed by dentists and then enlisted medical personnel in the Army and Air Force while in the Navy it was enlisted medical personnel with dentist in third place The largest understaffed group in the Army and Air Force was nurses In the Navy dentists led nurses by a small per cent in understaffing It is interesting to note that these results are almost identical with the report covering the last six months of 1954 <sup>1</sup>

**Types of Patients Treated** One of the questions concerned the percentage of time devoted by physicians to military personnel dependents of military personnel and administrative duties both at domestic and overseas stations Approximately 50 per cent of the reporting physicians said that they devoted one half or more of their time to military personnel both at domestic and overseas stations One half or more of the time allotted to dependents of military personnel at domestic stations was indicated by 36 per cent of the replying physicians and at overseas stations by 93 per cent

**Types of Nonmilitary Medical Care** The type of medical care most frequently performed by medical officers for nonmilitary persons was outpatient care Second in order of frequency for all three services was general medical and hospital care (although in the Navy "other specialty services" tied for second place) For the Army "other specialty services" was third in order with obstetrics and gynecology the third in order for the Navy and Air Force

**Medical Duties Performed by Others** One of the questions was designed to obtain information with respect to provision of medical care for dependents by other than military physicians The question was worded differently in the questionnaire form for the last six months of the period reported, consequently separate tabulations had to be made for each half of the period In the first six month reporting period over 50 per cent of the replying physicians believed that their duties could have been performed by other personnel Of this group over two thirds in each of the three services indicated possible transfer of their duties to civilian medical personnel In the second six month period there was a spread of 12 to 50 per cent between services in which the physicians indicated that none of their duties could have been performed by civilian medical personnel The great majority replied that some most or all of their duties could have been performed by someone else About 40 per cent of this latter

group in each service believed that all domestic duties could have been performed by civilian medical personnel

**Physicians Who Would Voluntarily Remain in Service** In response to the question relative to military service beyond the obligated tour of duty, 923 physicians indicated they would not be willing to stay in military service for more than their two years of service under any circumstances. A total of 1,203 physicians indicated they would serve an additional period under certain conditions. As expected, total war led the list of "certain conditions" for all three services, followed by "increase in pay." Other conditions on this list were choice of stable location or duty assignment, opportunity to practice specialty, and promotion to higher rank.

## NEW COMMANDING OFFICER AT LANDSTUHL ARMY MEDICAL CENTER

Brigadier General Clement F. St. John MC USA has assumed command of the Landstuhl Army Medical Center U S Army in Europe succeeding Colonel Paul Hayes MC USA who has returned to the United States. This marks the first time the Medical Center has had a Brigadier General in command. In addition to the organizations at Landstuhl General St. John's new command includes the Army hospitals at Neubruecke, Bad Cannstatt, and Frankfurt, Germany, and five ambulance trains. General St. John was Deputy Surgeon U S Army in Europe from June 1955 until he assumed his present command.

General St. John has a long and illustrious military career in various staff and command assignments. He served in North Africa in 1942 with General Patton's Western Task Force, participated in the amphibious invasion at Casablanca, and took part in the Fifth Army's invasion of Salerno in September 1943. He was awarded the Legion of Merit, Medal for Valor (Italy), and Commander of Royal Order of the Crown (Italy).

## NATIONAL INDUSTRIAL HEALTH CONFERENCE

The Twelfth National Industrial Health Conference will be held at Kiel Auditorium St. Louis Mo. 20-26 April 1957. These Conferences annually bring together the five organizations whose members are responsible for maintaining the health of the nation's industrial workers: the Industrial Medical Association, the American Industrial Hygiene Association, the American Association of Industrial Nurses, the American Conference of Governmental Industrial Hygienists, and the American Association of Industrial Dentists.

Some 200 of the country's leading specialists and experts in the complexities and technicalities of preventive medicine and hygiene in industry will present the latest findings and developments relating to occupational diseases and injuries, nonoccupational conditions in employment, mental health, psychologic testing, rehabilitation, and physical therapy, geriatrics and retirement, problem drinking, noise, air pollution, toxicology, radiation, administrative medicine, cancer as an industrial health problem, the relation of the general practitioner to industrial work, dental health, the medical witness in the courtroom, death patterns in industry, respiratory protection and engineering and analytical chemistry as related to industrial health, together with numerous other subjects of present day medical and scientific importance.

More than 100 technical exhibits will be displayed throughout the Conference. The exhibits are designed to acquaint the industrial physician with all the latest developments in products and equipment that will aid him in his work.

The formal sessions—more than 40 in number—include symposiums and panel discussions on subjects of timely interest, special meetings of the various groups, and conferences of special committees. In addition, there will be meetings of company physicians—steel, oil, electric, auto—starting with the all day conference of General Motors physicians on Monday, 22 April.

Feature of the formal opening session will be the C. O. Sappington Memorial Lecture by Frank Curtis, Vice President, Monsanto Chemical Company, and Past President, American Institute of Chemical Engineers. The Donald E. Cummings Memorial Lecture will be given by H. P. Schrenk, Ph. D., Industrial Hygiene Foundation.

The annual Industrial Health Conference provides an unexcelled opportunity for postgraduate study of new ways to improve and preserve the health of the American worker. Its purpose is the continuing

Individuals desiring to attend the course may submit an application in letter form through appropriate military channels to the Surgeon General Department of the Army Washington 25 D C Attn Personnel Division

## Army Medical Officer Honored

Colonel William L Thompson MC USA (Ret) was honored on 9 February at a meeting of the annual combined session of the American College of Radiology and the Association of Teachers of Radiology at the Drake Hotel Chicago Ill He was presented a Special Award of Honor by the Board of Chancellors of the American College of Radiology for his outstanding achievement as Chief of the Registry of Radiologic Pathology at the Armed Forces Institute of Pathology The award read in part

Colonel Thompson exemplifies the highest attainments of judicious perceiving effort motivating the outstanding medical scientist His contributions to radiological education and training are invaluable his efforts on behalf of our specialty are beyond recompense the gratitude of his colleagues and friends is without qualification We all are in his debt

Colonel Thompson has been with the Armed Forces Institute of Pathology since his retirement in June 1950 as Chief of the Radiologic Pathology Section of the American Registry of Pathology

All dentists stationed at the Little Rock Air Force Base are members of the American Dental Association and take an active interest in district and state association affairs

## CORRESPONDENCE

*The article by Lieutenant Colonel John W. Burkett MC USA on "Clinical Recognition of Early and Insidious Schizophrenia, which was published on pages 1759 to 1763 of the December 1956 issue of this Journal appears to have aroused considerable interest. It was abstracted on page 54 of the 31 December 1956 issue of Newsweek and also evoked a letter to the editor that we consider to be a well thought out extension of Colonel Burkett's position—Editor*

*To the Editor —Dr. Burkett's article has not failed to leave a definite imprint on the thinking and feeling of the medical staff at these writers' duty station, a major naval hospital called upon to evaluate and treat a good number of schizophrenics. Not only psychiatrists but also general medical officers have a frequent occasion to encounter similar problems and it is their concern with the matter that led these writers to give a brief answer to the ideas expressed in the article.*

Quite judiciously, Dr. Burkett pointed out that a variety of symptoms can be the early signs of schizophrenia. He also stated explicitly in the summary that none of these are by themselves pathognomonic for the disease, yet the emphasis placed on them has aroused understandable concern in many medical officers who daily see these symptoms and at once come to suspect a deep seated psychosis instead of a mild neurotic symptom that should be handled supportively. It is a not unusual experience on neuropsychiatric services of hospitals like this one to receive intransfer patients who have already been given diagnoses of schizophrenia when the problems in reality are the consequence of character disorders of various kinds. Under appropriate management they typically quiet down within a day or two and this opens the way for further treatment and/or judicious disposition.

In order to clarify the issue of early schizophrenia and its recognition a few considerations seem to be appropriate. In present day thinking schizophrenia is generally seen as a malignant disorder of thinking the main feature of which is a disintegration of the personality structure. The process may progress steadily, may remain stationary, or may reverse itself with more or less full recovery. Its main characteristic is the *depth* of the disturbance and not its manifestations. Bleuler's distinction between the primary and secondary symptoms although now partially superseded by newer research makes this particular point very clear. The psychoanalytically oriented psychiatrists, moreover, have shown that the problems with which schizophrenic patients

---

Bleuler E. P. *Textbook of Psychiatry*. Author ed. English edition by A. A. Brill.  
Dover Publications Inc. New York N.Y. 1951.

grapple are basically the same as those of the neurotics and of mankind in general. It is only their way of dealing with them which reveals the actual breakdown of the personality structure. The so called defense mechanisms or the ways of dealing with problems, are many and varied, and it is well accepted that normal people, neurotics, and schizophrenics can use the same kinds. Unfortunately therefore we cannot classify certain kinds of reaction patterns simply as schizophrenic or neurotic.

There is however a difference in obviousness which can serve as a guidepost for any examiner who is called upon to evaluate a man's mental disease in a short and practicable time. Frank delusions, as everyone knows, are likely to be schizophrenic, in the absence of toxic or organic findings. Distortion of reality and projection often occur in psychotics in an obvious form. Yet they can occur in neurotics also, although sometimes difficult to discover. Anxiety in various forms, such as "shaking spells," apprehension, or manifest physical signs, is also a fairly common human response under certain stresses, and the task of the physician is to evaluate its depth and its disruptive threat. Deep, free floating anxiety that does not subside when the secondary gains of a neurotic are realized, will strike anyone as more serious than the bidding of an immature personality to be freed of a stressful situation. The apparent absence of immediate secondary gain will often be a signpost toward a more malignant diagnosis. Schizophrenics often request return to duty in the face of obvious inadequacies in their functioning, whereas the more frequent character disorders will invariably seek discharge from service, in spite of their capacity for apparently satisfactory functioning.

It is not the purpose to establish solid and specific criteria for the diagnosis of early schizophrenia. This, in the writers' opinion, cannot be done at the present time when competent psychiatrists still hold many contradictory opinions. For the service medical officer required to assess a patient's mental symptoms quickly and accurately, certain main features must be kept foremost in his diagnostic thinking. They seem to us to be (1) the depth of the personality disintegration often correctly assessed by the patient's immediate associates, (2) the conspicuous pathology of certain defense mechanisms like distortion of reality and projection, and (3) a primitive type of anxiety which is unaffected and unalleviated by secondary gains and often appears incomprehensible or inappropriate to the casual examiner.

The author has, however, aroused considerable alarm among non-psychiatric medical officers by emphasis upon the nonspecific signs and symptoms of incipient (not borderline) psychosis. These general service medical officers are now naturally but unjustifiably doubtful of their ability to assess the importance of anxiety, hypochondriasis, conversion symptoms, and alcoholism. Since it is probably more damaging to the patient to be labeled psychotic in error than to defer a firm diagnosis, even though appropriate treatment may be thereby postponed, it is probably most prudent to continue leaving the diagnosis of incipient

psychoses and borderline states to the experienced psychiatrists. While early recognition and treatment are surely desirable in all branches of medicine this problem has little if any emergency importance such as found in acute surgical crises

Dr Buxett has performed a useful service in stirring interest in and discussion of an important aspect of psychiatry

## Air Force Nurse Awarded Legion of Merit

By direction of the President Captain Antoinette M A Fears USAF (AC) has been awarded the Legion of Merit for exceptionally meritorious conduct in the performance of outstanding service in the Caribbean Air Command during the period 10 August 1954 to 18 July 1956.

Captain Fears in 16 emergency or rescue missions with the U S Air Force Air Sea Rescue Service rendered distinctive and professional services displaying disregard for her own personal safety in the face of very hazardous conditions. On several occasions her outstanding performance was directly responsible for the saving of a life. Captain Fears has reflected a great credit upon herself and the Medical Service of the United States Air Force.

## Reviews of Recent Books

A TEXTBOOK OF PATHOLOGY by *E T Bell* M D Contributors *B J Clawson*, M D, and *J S McCartney* M D 8th edition 1 028 pages 545 illustrations and 5 plates in color Lea & Febiger Philadelphia Pa 1956 Price \$14 50

This new edition follows the same pattern of organization and development of general and systemic pathology as did the seventh edition. There have been alterations and additions reflecting recent advances and developments particularly in the hematologic and metabolic sections. References to recent contributions to the literature are made with a large proportion dating back to 15 to 20 years ago.

The text is well organized and is clearly and comprehensively written. Its numerous illustrative photomicrographs, drawings and plates are well chosen. Its presentation is consistent with the needs of the medical student, the resident and the clinician desiring a concise review of the basic principles of pathology with a minimal emphasis on problematical and controversial issues.

—NELSON S IREY Lt Col MC USA

ETIOLOGIC FACTORS IN RENAL LITHIASIS compiled and edited by *Arthur J Butt* M D F A C S 400 pages illustrated Charles C Thomas Publisher Springfield Ill 1956 Price \$12 50

This is an excellent and timely review of the factors in the etiology of urinary calculi. Dr Butt, while acting primarily as editor, has also contributed certain chapters from his vast experience in this field. The remaining chapters have been prepared by 20 contributors prominent in the field of urology and urologic research.

The subject is one of the oldest in the field of medicine. Although the book does not say the final word concerning the etiology of calculi, it does assemble a mass of information that cannot be found elsewhere in one volume. At the close of each chapter, many references are made to the literature from which the opinions are formed. The contributors frankly present divergent views so that one can form his own opinion regarding the etiologic factors of stone formation.

The book goes into the newer uses of the electron microscope and the flame photometer with reference to urinary colloids, and one chapter is devoted to the analysis of stones. It covers stasis, retention, metabolic disturbances, diet and environment in relation to stone formation. It leaves open the possibility that there still exists a common denominator for all stone formation which to date has not been found.

The editor brings out the fine original work which he has done with reference to hyaluronidase and the consequent release of hyaluronic acid

This is an excellent work for all interested in research on the subject of renal lithiasis particularly for those desiring to study the causes It should serve as a springboard for further studies in the field

—JOHN A SCHINDLER Col USAF (MC)

NEUROLOGICAL NURSING A Practical Guide by John Marshall M D  
M R C P M R C P Ed D P M 166 pages illustrated Charles  
C Thomas Publisher Springfield Ill 1956 Price \$3 75

This textbook is intended for nurses doctors physiotherapists and others who are concerned with the general management of patients suffering from neurologic disease The author points out that the nurse has an important part to play in the wider therapeutic approach to neurologic diseases and a responsibility for educating the patient in the management of his disability

This small 166 page textbook does not attempt to deal with detailed accounts of the anatomy and physiology of the nervous system or with extensive descriptions as signs and symptoms of neurologic disease It is entirely concerned with the practical problems encountered in the care of these patients Clear and concise instructions in the management of neurologic problems including specialized techniques are outlined for the nurse The book is well illustrated with black and white photographs and excellent sketches demonstrating proper positioning of the patient There is a particularly noteworthy chapter on the psychologic approach to the patient with neurologic disease This text is strongly recommended for both student and graduate nurses

—VERA E THOMPSON Lt Comdr NC USN

CONCISE ANATOMY by Linda F Edwards Ph D 2d edition 507 page  
illustrated McGraw Hill Book Co Inc New York N Y 1956 Price  
\$6 50

In 502 pages the author has covered the field of human anatomy in a surprisingly detailed manner As one would expect from the title the book lacks the greater detail and reference value of a *Gray's Anatomy* or of other standard texts Following a short introduction the book is divided into six parts dealing with general anatomy the superior extremity the inferior extremity the head the neck and trunk and the splanchnic structures At the end of each chapter there is a brief discussion of applied anatomy Descriptions of anomalies and the relationships of the various structures are brief or omitted

The text is written in a clear concise and readable manner Except for a colored plate of normal blood cells the illustrations are all black and white most are from *Morris Human Anatomy* The illustrations are

generally adequate, but a few could be improved by color. The printing and binding are well done. Because it lacks many details found in the larger texts, the book is not recommended for medical students or as a reference work. However, nurses and students of the biological sciences generally will find this a useful text.

—HUGH B. HOEFFLER Lt Col MC USA

**PEDIATRICS** edited by *Donald Paterson M D* and *John Ferguson McCreary M D* with 36 contributing authors. 654 pages illustrated. J. B. Lippincott Co. Philadelphia, Pa. 1956. Price \$14.

The work of a number of Canadian authors, this 654 page textbook is easily read and well indexed and should appeal first to the general practitioners of medicine. There are numerous illustrations of good quality and a complete bibliography. Emphasis is placed on diagnosis and treatment of the commoner conditions, with rarities being mentioned but not elaborated on. The section on poisoning could be more complete and that on fluid and electrolyte more detailed. Problems of the newborn, ophthalmic and orthopedic, receive suitable attention in the text with many ophthalmic illustrations which are excellent.

Considering diseases due to prenatal factors, an excellent table is provided listing the clinical disease, approximate incidence, and pedigree pattern. The commoner problems of the alimentary tract are well presented together with excellent roentgenograms. A thoughtful discussion of the respiratory system is given with many good roentgenograms of the major problems. Allergies, asthma, allergic rhinitis, and eczema receive good coverage. The anemias of infancy and childhood are discussed well and also presented in tabular form.

Diseases of the nervous system, mental retardation, and behavior disorders receive practical consideration in this volume while at the end of the book there are tables of drug dosage, blood plasma and serum values, liver and kidney function tests, and various suggested diets. The book is well written, orderly, and practical.

—MILTON KURZROK Capt MC USN

**PROGRESS IN RADIOBIOLOGY** Proceedings of the Fourth International Conference on Radiobiology held in Cambridge on 14th to 17th August 1955, edited by *Joseph S. Mitchell*, *Barbara E. Holmes* and *Cyril L. Smith*. 557 pages illustrated. Charles C. Thomas, Publisher, Springfield, Ill. 1956. Price \$12.75.

This volume is the record of the Fourth International Conference on Radiobiology convened at Cambridge, England, in August 1955. The authors have attempted to present a coherent, readable picture of the Conference and have reprinted a good deal of discussion by the delegates after each paper. The inclusion of this detailed discussion is unusual in formal publications, but, for this reviewer, added immeasurably to the value of the papers and was well worth the editorial effort.

The data presented is almost entirely new and includes the contemporary work of over one hundred radiobiologists representing 20 countries. Subject material encompasses a significant portion of the field including biochemical and enzymatic applications as well as effects on the total subject from bacteria to man. Special sections are devoted to genetics, carcinogenesis, protection and human data. Throughout the book emphasis is on the relationship of radiobiology to the field of clinical medicine and where appropriate practical extensions of laboratory work are suggested or recommended. Some of these suggestions are certainly tentative but it is refreshing to see the development of a closer relationship between the biologist and the clinician.

Although this book is of primary value to the radiobiologist it is felt that the radiologist as well as other physicians interested in the effects of radiation on man will find many of the fundamental principles discussed clearly and concisely and will gain an appreciation of some of the current problems and controversies.

—JAMES B HARTGERING Lt Col MC USA

**DIABETES MELLITUS** Handbook for Physicians by Howard F Root MD, Sc D, F A C P and Priscilla White MD, Sc D, F A C P 346 page. Landsberger Medical Books Inc New York N Y 1956 Distributed solely by The Blakiston Division of the McGraw Hill Book Co Inc New York N Y Price \$7

This book is meant to be a handbook for the daily use of physicians and accomplishes its object very well. It succeeds in giving a good picture of all the usual findings in the disease as well as giving a brief but good account of many complications. Since it is intended to be practical and immediately useful it is somewhat didactic but mentions alternate procedures usually giving the authors arguments against them.

The authors point out the value of determining the postprandial blood sugar as against the standard fasting test. They call attention to the need for complete examination of the patient who may have a variety of symptoms caused by diabetes. The book points out the need of repeated follow up and observation. Diet is handled in a short sensible chapter. The early use of insulin in the disease is urged on the basis that the patient will appreciate that his disease is serious and requires constant attention.

There is mention of the new insulin saving sulfonamide derivatives the usefulness of which is still being investigated. Especially interesting were the observations on diabetic neuropathy. The relationship of infections, anesthesia and surgery to insulin resistance is discussed. The danger of nephropathy in long term diabetics is brought out as well as the handling of diabetics facing operation.

There is ample space given to the endocrine method of treating pregnant diabetic women with statistics of the excellent results obtained by the authors. This method has not been always successful in the hands of others.

The authors have followed a great number of diabetic children for many years, and the inevitability of vascular and kidney damage is obvious. The authors are optimistic that future discoveries may improve this picture. This is an impressive and useful little book which any physician would enjoy. —JAMES L. TOBIN Col USAF (MC)

**HEAD INJURIES AND THEIR MANAGEMENT** by Francis Asbury Echlin, M D C M M Sc Med Sc D F A C S 127 pages illustrated J B Lippincott Co Philadelphia Pa 1956 Price \$3

This small handbook briefly describes the essentials in diagnosis and treatment of head injuries making this knowledge easily accessible and of practical value to interns residents and surgeons.

Sections on the mechanisms of head and brain injury nonsurgical lesions of the brain and surgical conditions such as lesions of the scalp skull fractures hematomas and penetrating wounds of the brain, surgical complications of head injuries, such as wound infection skull defects, and posttraumatic epilepsy give concise but little more than introductory discussions of the problems. The diagnostic procedures of encephalography and angiography are little more than mentioned.

Even as a guide the book is inadequate and will not fit the needs of a physician on whom rests the responsibility of diagnosing and treating head injuries. —FRANKLIN M. ROBERTS Lt MC USNR

**SIMPLIFIED NURSING** by Florence Dakin R N and Ella M. Thompson B S R N, with the assistance of Margaret LeBaron R N 6th edition 800 pages illustrated J B Lippincott Co, Philadelphia Pa, 1956 Price \$4.50

This book has been revised and brought up to date to keep pace with new developments in medical care and the changing concepts in the training and the utilization of practical nurses in the home and the hospital.

The format is essentially the same as in earlier editions but much new material has been added. More information has been included concerning the structure and functions of the body. Since the development of many new drugs affecting the treatment and care of patients the section on drugs has been considerably increased.

Other material revised in this comprehensive text includes the status of the practical nurse as a member of the health team in the hospital and the community. Throughout the book emphasis is placed on the care of the patient as a person—a human being who has personal problems and emotional reactions—and on the need for the practical nursing student to make personal adjustments and establish good report.

In the presentation of nursing procedures the two column format which includes "Suggested Procedure" and "Key Points" has been

retained. The whole text is easily read and very understandable making it particularly valuable to the student practical nurse. There is an excellent detailed index and a list of references for further study.

This book is highly recommended as a useful guide for the instructor of auxiliary nursing personnel as well as a text for the practical nursing student. —AILEEN E. BRIMMER Maj USAF (MC)

**PRACTICAL PEDIATRIC DERMATOLOGY** by Morris Leider M D 433 pages 260 photographs and 13 drawings. The C. V. Mosby Co. St. Louis Mo. 1956. Price \$10.50.

This book, a first edition, will be most appreciated by the busy pediatrician and general practitioner. Although embracing very little that is new or original in the management of skin diseases in children, the frequent use of charts and tables in presenting the material will be a timesaver for many. It is not intended to replace the more encyclopedic works for the specialist, but is written with practical purposes foremost in mind. Even so, the author admits encountering difficulty in deciding what subject material to omit from the book.

The final chapter attempts to cover a miscellany of uncommon dermatoses of infants and children. In this one chapter over one hundred dermatoses are briefly described.

The book is arranged in 14 chapters, generally grouped according to broad etiology. It is completed in 433 pages. The photographs are good. —CLAUDE B. WHITE Col USAF (MC)

**THE YEAR BOOK OF PEDIATRICS (1956-1957 Year Book Series)** edited by Sydney S. Gellis M D 480 pages illustrated. The Year Book Publishers Inc. Chicago Ill. 1956. Price \$6.75.

This book is a representative review of the American and foreign pediatric literature from June 1955 through May 1956. This volume is similar to and compares favorably with previous and companion volumes. The abstracts are conveniently arranged according to the body systems in 18 well indexed sections. The editor has done very well in preparing and compiling 335 abstracts of the best and most representative papers in the current pediatric literature. The volume is suitable as a quick and ready reference and as a guide to determine the trend in recent pediatric treatment and diagnostic methods.

Dr. Gellis is to be congratulated for accomplishing the Herculean task of abstracting and compiling pertinent pediatric literature in such a complete, convenient, and well organized manner. One of the most valuable features is the editorial comment following most of the more important papers presented. The value of this volume is greatly enhanced by the interspersing of comments by many guest authorities on the more controversial subjects.

This book is recommended for all students and physicians interested in the most up to date information in the field of pediatrics. While not a reference book it presents much practical information in a concise and readily accessible form. —WILLIAM I NEIKIRK *Comdr MC USN*

**A GUIDE FOR PSYCHIATRIC AIDES**, by *Charlotte R Rodeman R N M Ed*  
234 pages The Macmillan Co, New York N Y 1956

This book is of great value to a nursing instructor who is responsible for the training of nonprofessional personnel assigned to the care of psychiatric patients. It also provides an excellent guide for the individual worker. The text is well written in clear understandable terms which can easily be grasped by the beginner.

The author has continually emphasized the attitudes and relationships of the attendant in respect to the nursing care to be administered. The material is divided into 11 chapters followed by a glossary, bibliography, and index.

Since tranquilizing drugs are now being used effectively in the treatment of psychiatric patients the value of this book as a guide might be increased by adding another chapter on nursing care in this area. Despite this however the book is excellent and should be well received.

—ELEANOR WELCH *Maj USAF (NC)*

**CLINICAL ENDODONTICS** A Manual of Scientific Endodontics by *Ralph Frederick Sommer D D S M S F A C D F A A O R F* and *Darl Ostrander A B D D S M S F A C D* and *Mary C. Crouley A B M S P H* 514 pages illustrated W B Saunders Co Philadelphia Pa 1956 Price \$10.50

In the preface the authors state that it is their intention to approach the subject of endodontics by integrating the preclinical demonstrations with the actual clinical practice. It is the reviewer's belief that this is accomplished in an extremely satisfactory manner.

The book is divided into 22 chapters which cover the subject from a history of root canal therapy to a brief discussion of the principles of prescription writing. Not only does this book discuss the technique of root canal management but also the histology and histopathology of the dental pulp and periapex.

Line drawings, x rays, and photographs are well related to adequately develop each new subject. The x rays are particularly worthy of note, they are well chosen, clearly reproduced, and are provided with brief and clear legends.

Chapters devoted to the fields of bacteriology and pharmacology are very well done and will be of great value to general practitioners as well as endodontists. Included is an up to-date review of the antibiotics and chemotherapeutic agents. In the chapter devoted to the roentgenographic diagnosis of periapical lesions the authors clearly dispel a

misconception regarding the ability of the clinician to differentiate radicular cysts from dental granulomas by x ray. The separation of these lesions by histologic examination is emphasized. This information is available because of the co-operation of the authors with a very able oral pathologist. The reader will find this chapter stimulating as well as illuminating.

This book is to be recommended to all general practitioners of dentistry, endodontists and senior dental students.

—WILLIAM G. SPRAGUE, Capt. USAF (DC)

PERSONALITY, STRESS AND TUBERCULOSIS, edited by Phineas J. Sparer.  
M. D. 629 pages, illustrated. International Universities Press, Inc., New York, N. Y., 1956. Price \$12.50.

This book brings together selected topics by authors well qualified to review current thought, practice and research in the various fields related to tuberculosis. Chapters on the psychiatric, psychological and psychosomatic, as well as physicochemical and endocrine aspects of the disease are included. Considerable material of practical significance is discussed, including irregular discharges and rehabilitation. The many problems that arise in relation to the alcoholic tuberculous patient are well presented.

In a volume of this type there is of necessity considerable repetition of material, especially in those chapters discussing the personality attitudes and emotional reactions of tuberculous patients.

While there is little that is actually new in this volume for those who are working actively in the field and staying abreast of the current literature, it should serve as an excellent review of the interdisciplinary approach to the tuberculous patient. The book will also prove extremely valuable as a ready reference volume because of the comprehensive review of the literature.

One criticism might be that too little space is given to the problem of motivation in these patients. One wonders what the recovery rate might be if a sizeable monetary award were given for recovery. It is fairly well proven that service-connected cases tend to leave the hospital before recovery rather than lose their service-connected monetary disability benefits. The early monetary settlement of accident claims by insurance companies has certainly tended to definitely reduce chronic invalidism in many cases.

It continues to appear that we may well have been wrong in fostering regression in the active tuberculous patients. The old days of absolute bed rest may finally be replaced by physical activity within reason. This book is strongly recommended for all those who are interested in the successful treatment of the tuberculous patient.

—PHILLIP B. SMITH, Lt. Col., A. C., USA

**PREPARING FOR MOTHERHOOD** A Manual for Expectant Parents by  
*Samuel R Meaker* M D 196 pages illustrated The Year Book Pub-  
lishers Inc , Chicago Ill 1956 Price \$2

This manual for expectant parents presents stimulating and detailed helpful advice for every expectant mother from the time of conception through the puerperium. It is designed to educate the parents and create understanding and co operation between them and their attending obstetrician.

Its 200 pages are written in an easily readable and personal style by Dr Meaker who has thoughtfully presented information adaptable to and supplementary to any of the usual methods of prenatal and obstetrical management. He adequately covers all the information expectant parents need to know including early and late signs of pregnancy expected physical and psychologic changes precautions and care during various stages of pregnancy methods and reasons for psychologic preparation for labor and for various analgesics and anesthetics the relief of common discomforts and many other details.

Dr Meaker has succeeded in giving us a welcome complete and pleasantly styled manual to supplement physicians advice to their patients —*DWIGHT A. CALLAGAN* *Comdr MC USN*

**ATLAS OF PLASTER CAST TECHNIQUES** by *E E Bleck* M D *Nellie Duckworth* and *Nancy Hunter* 128 pages illustrated The Year Book Publishers Inc Chicago Ill 1956 Price \$4 75

This manual is intended for the novice in plaster technics and the occasional user of plaster immobilization. It is presented in the form of a spiral binder and printed on heavy glossy paper. In addition to the discussion of extremity and body casts it contains chapters on plaster of parts plaster room equipment general technics wedging casts complications removal of plaster casts bibliography index and a concise appendix covering supplies their sizes and sources.

The narrative part of the manual comprises less than 20 per cent of the space the bulk of the material is presented in the form of a series of excellent step by step photographs accompanied by concise legends.

Technically the authors have well achieved what they set out to do to be of help to internes residents plaster nurses and plaster room orderlies.

The material discussed carries considerable authority springing primarily from 32 years experience at the North Carolina Orthopedic Hospital where most of the basic ideas presented were developed. But beyond that much that was developed and refined in the South is incorporated such as the Hoke Well Leg Traction or Kites Wedging Cast Treatment for the congenital clubfoot.

Brevity and clarity of presentation enhance the definite value of this work —*ERNST DEHNE* *Lt Col MC USA*

THE MERCK MANUAL of Diagnosis and Therapy edited by Charles E Lyght  
M D 9th edition 1888 pages 20 main sections each thumb-indexed  
Merck & Co Inc Rahway N J 1956. Price \$6 75

As most medical students and house officers know a great variety of information is readily available in this small compact book It is an immediate on the spot guide with reference to current literature and standard texts for more complete discussions The manual provides up to-date medical information in a convenient concise yet adequate form

The format of the new edition is similar to that of the 1951 edition Diagnosis and therapy are given primary emphasis but pertinent physiologic pathologic and etiologic factors are included Readily applicable advice on the treatment of medical emergencies burns poisoning and shock greatly enhance its usefulness In addition to several new chapters many new illustrations diagrams and tables have been included

A more complete and useful handbook covering such a wide variety of general medical subjects is not available in any book of this size  
—FRANKLIN M ROBERTS Lt MG, USNR

HOMOSEXUALITY Disease or Way of Life? By Edmund Bergler M D 302 pages  
Hill and Wang Inc New York N Y 1956 Price \$5

The author contends that there are four factors which have made the problem of homosexuality more important for us today than it was 10 years ago First there has been some awakening to the seriousness of the problem even though there is still great general ignorance on this subject Second there are many incipient homosexuals who have become confirmed homosexuals through the dissemination of inaccurate false and misleading information Third homosexuality is at the root of a new and increasing kind of marital tragedy that in which a homosexual marries an unsuspecting male The most important of the four premises is that homosexuality is a psychiatric illness coming into the area of treatment and cure In this book the four points indicated above are projected in the light of Dr Bergler's vast psychoanalytic experience There is much illustration and amplification of his view of the psychodynamics psychopathology and psychoanalytic treatment of both male and female homosexuals

At times this reviewer felt that Dr Bergler might better have written two books one for lay consumption and one for professional readers Much of the psychoanalytic material seems too complex too repetitious and too unenlightening for the lay reader while there is some material which is old and somewhat boring for the psychiatrist  
This book is recommended to the medical profession and to the lay reader who requires more information on the subject  
—ROBERT E SWITZER M D

**THE YEAR BOOK OF OBSTETRICS AND GYNECOLOGY** (1956-1957 Year Book Series) edited by *J P Greenhill* MD FACS FICS (Honorary) 592 pages illustrated The Year Book Publishers, Inc, Chicago, Ill, 1956 Price \$6.75

This book merits nothing but high praise. It is in an easily readable style, the abstracts cover the domestic and foreign literature from July 1955 to July 1956 and give the essence of the original article effectively. The frequent editorial footnotes reflect a conservative approach to the problems in this field and also a great wealth of personal experience.

The Year Book can serve as "the bible" for the busy general practitioner as well as the residents and specialists in this field.

—HENRY J HUNTER Capt MC USN

**GLAUCOMA** Transactions of the First Conference December 5, 6 and 7 1955 Princeton N J Edited by *Frank W Newell* MD Sponsored by the Josiah Macy Jr Foundation New York N Y Josiah Macy Jr Foundation Publications New York N Y, 1956. Price \$4.50

The goal of these conferences, as organized by the Josiah Macy Jr Foundation, is to bring together scientists for the promotion of communication and exchange of ideas on research dealing with some urgent problem in medicine and health. This book deals with the subject of glaucoma. The transactions are published in order to share the conference process with a larger audience than could participate personally.

The format of the book is excellent. It is divided into three sections: (1) a review of angle-closure glaucoma, (2) central control of intraocular pressure, and (3) physiologic and pharmacologic factors influencing the resistance to aqueous outflow. Each subject is introduced by an authority who acts as chairman for the discussion, and the dialogue is printed verbatim. The discussion may proceed along a single viewpoint, or it may veer off in a different direction as the influence of an allied scientist becomes evident. At the end of each section there are voluminous references which are excellent source material for the researcher, teacher, and ophthalmologist. The first section will hold more interest for the practicing ophthalmologist than the others, particularly the discussion dealing with classifications, trigger mechanism, and interrelationship of blood pressure and intraocular pressure.

The other two sections will hold more interest for the researcher and teacher in the field. It is believed that this style of conference technique will prove interesting and stimulate discussion. Some will object to their trend of thought being interrupted, and the discussors inability to arrive at conclusions. A good deal of time and space is consumed in the explanation of research apparatus and techniques.

The book is definitely applicable for the research and teaching ophthalmologist. While the average practicing ophthalmologist will not find its contents readily usable, he will find his interest and greatly aroused and his powers of observation and ledge enormously increased. —AUBREY L JENNINGS Col MC

**SURGERY FOR GENERAL PRACTICE** by Victor Richards M D 947 page  
476 illustrations The C V Mosby Co St Louis, Mo 1936 Price  
\$17 50

This text on surgery encompasses almost the entire field of surgery ranging from seemingly minor ailments to life-endangering catastrophes. The book is well written readable and is adequately illustrated with clean and simple black and white sketches and drawings. The author has written the major portions of the book drawing on over 10 years experience at the Stanford University Surgical Outpatient Clinics.

The majority of chapters are prefaced with clear and concise discussions on applicable anatomy basic physiology and/or general concepts of treatment. For each condition discussed the author usually mentions several of the presently accepted modes of treatment dwelling a slightly greater length on one of these modes. Although this is not a book of operative technics many so called minor technics for office work are described in detail.

The author has done an admirable job discussing present day concepts of pathologic physiology diagnosis and treatment. It is felt that this book will be valuable to physicians in general practice and will help them understand evaluate and treat surgical condition — CLINTON S LYTER Col MC USA

**PRESCRIPTION WRITING AND MATERIA MEDICA FOR DENTISTS** by  
L. Richard Cipes Ph.G DDS 4th edition 624 pages illustrated  
Dental Items of Interest Publishing Co Inc Brooklyn NY 1956  
Price \$9 50

In revising the third edition, the author states that it is the responsibility of the conscientious dentist to acquaint himself with the new drugs and their administration for the relief of pain control of infection and treatment of other conditions affecting the state of health of the oral cavity and the individual.

In logical sequence the author gives the prescription writing the reasons for prescribing the materia medica of dentistry and the method of prescribing drugs.

The section on antibiotic therapy is an excellent reference and the chapter on dental formulas gives much useful information. The author has included a very comprehensive section on prescription writing from which all dentists can benefit.

This book is well written in a clear concise and easily readable style. The type paper and binding are good. The illustrations tables and graphs are clear and pertinent. A short but adequate list of references is given.

This book should provide interesting and useful information to the dental student and practicing dentist and offers a good reference to dental materia medica — RICHARD J BURCH Col USAF (DC)

**ADRENAL FUNCTION IN INFANTS AND CHILDREN** A Symposium edited by Lytt I Gardner M D 221 pages illustrated Grune & Stratton Inc New York N Y , 1956 Price \$6 75

This book is a complete transcription of a symposium held in Syracuse N Y , in November 1954 At this meeting an attempt was made to correlate what is known of adrenal function in infants and children It succeeded beautifully The subjects covered vary from those of academic and theoretic interest such as the origin of the ketosteroids and the nature of the enzymic deficiencies in the adrenogenital syndrome to subjects of considerable clinical interest and importance such as the surgical treatment of pseudohermaphroditism Throughout all the various sections of the book one finds bits of information which are not available elsewhere and which are important to people working in the field for instance, the difference in the pattern of excretion of 17 ketosteroids in premature and full term infants The book has been carefully edited with the important discussions being presented verbatim These are of great interest for they illustrate the differences of opinion among the authorities in this field and the vast areas which remain to be investigated before the problem of adrenal function in children can be clearly understood If the book has any deficiency, it lies not in the work of several authors or the editor but in the undeveloped state of our knowledge at the present time

—DANIEL STOWENS Maj MC USA

**The Laboratory Diagnosis of COAGULATION DEFECTS** by Pietro De Nicola, M D A Monograph in The Bannerstone Division of American Lectures in Pharmacology edited by Chauncey D Leake Ph D 240 pages 62 illustrations and 26 tables Charles C Thomas Publisher, Springfield Ill 1956 Price \$7 50

The author of this volume by virtue of his wide experience in the experimental and clinical field of coagulation defects is well qualified to analyze and present the complex physiology and physiopathology of this field The problem is a difficult one in that work in this field is continuing at a rapid pace Dr De Nicola has approached this problem by dividing his book into five parts Physiologic background description and interpretation of the general methodology special diagnosis of coagulation defects analytic description of the technics employed and a summary The first three sections are exceptionally well presented and serve as an excellent reference manual for the study of the problems of hemostasis The technical section suffers from the fact that the author is such an excellent technician himself and his descriptions of the diagnostic tests presume that the reader has had some experience in this field The neophyte might have some difficulty The section does contain five excellent tables on equipment and reagents required for the 30 tests described A selected bibliography is included This volume is recommended to coagulationists and others who are faced with the problem of unraveling problem in hemostasis —JOSEPH H AKEROYD Lt Col MS

WIRE BRUSH SURGERY In the Treatment of Certain Cosmetic Defects and Diseases of the Skin by James W. Burks Jr. M. S. M. D. American Lecture Series Publication No. 300 A Monograph in the Binnerstone Division of American Lectures in Dermatology edited by Arthur C. Curtis M. D. 154 pages illustrated Charles C. Thomas Publisher Springfield Ill. 1956 Price \$6.75

It is intellectually stimulating to review a monograph such as this one written in such an interesting and concise manner on the well advertised procedure of skin planing. The monograph presents from a medical standpoint the detailed facets of wire brush surgery from its history through future trends including anatomy, histopathology, psychology, equipment, anesthesia, and technique. It will prove to be of interest to physicians with experience in the procedure and of an absolute necessity to students and other physicians thinking of initiating this procedure in their clinics or practices.

The two purposes of this monograph—to summarize the experience of the pioneers in abrasive surgery and to present the author's personal experience in over 750 planings—have been accomplished. The author's attempt to apply academic knowledge of the basic sciences to the clinical procedure has also substantially succeeded.

Certain differences of opinion are bound to arise among physicians experienced in this procedure. The author himself was not too clear about whether to bandage or not to bandage. In the chapter "Psychological Aspects of Planing" the use of bandages is recommended in certain instances and for certain periods as is the use of an antibiotic ointment. However, in the chapter on "Postoperative Care" bandaging is not recommended, which I believe is in agreement with other experienced operators. The author also presents the belief that a fundamental psychological change can be expected as a result of planing. In my experience a superficial psychological change has proved to be the rule.

In one chapter lesions other than scars are discussed. Some of these include nevi, epitheliomas, and lupus erythematosus. This portion of the book is particularly suited to dermatologists and others with long experience in the diagnosis of skin lesions. I believe it should be emphasized that the results of planing epitheliomas in the author's hands may be entirely different than in those treated by relatively inexperienced operators. Positive diagnosis of all cases of nevi, tumors, and other conditions should be made prior to any decision concerning treatment.

The black and white photographs are excellent; all procedures are well illustrated. This monograph is a primer for all interested in the technique of skin planing.—ROBERT E. LYONS, Col. USAF (MC)

**CONTROLLED HYPOTENSION\* IN ANESTHESIA AND SURGERY** by David M. Little Jr. M.D. A Monograph in The Bannerstone Division of American Lectures in Anesthesiology edited by John Adriani M.D. 159 pages illustrated Charles C. Thomas, Publisher Springfield, Ill. 1956 Price \$4.50

With the present day trend toward wide variations in the practice of anesthesiology and the attempts to alter patients' normal physiologic responses by drugs and techniques so as to provide apparently better surgical fields it is wise to step back occasionally and review our actions. That is the aim and accomplished purpose of this monograph. Dr. Little has first presented the problem which is blood loss during operation, with a brief discussion of some of the major causes. This is followed by a discussion of the control of bleeding. He outlines several methods of control by the production of hypotension.

Because deliberately produced hypotension is very recent in the practice of anesthesia and surgery few physicians have extensive experience in this technic. The comprehensive review of the literature therefore is sufficient of itself to make this monograph worthwhile. The medical reports are co-ordinated with the practical application of the principles. The chapter discussing the side effects on the vital organs and those chapters presenting the indications, contraindications, and complications have concise conclusions and leave no doubt as to the author's opinions concerning the use of hypotensive techniques.

The reviewer believes that this monograph should be included in the reference library of all physicians who are directly concerned with the care of those patients who seem to require hypotension for the accomplishment of necessary surgical procedures. Since rational and conservative use is advocated the reviewer also believes that definite patient benefit may be obtained by using the monograph as a guide in such practice. —HOWARD A. PEDIGO Lt. Col. MC USA

**DIAGNOSTIC METHODS IN VETERINARY MEDICINE** by George F. Boddie B.Sc. (Edin.), M.R.C.V.S. F.R.S.E. 4th edition 412 pages illustrated J.B. Lippincott Co. Philadelphia, Pa. 1956 Price \$6.50

The author, Professor of Veterinary Medicine at Edinburgh University, Scotland, has directed this book toward the veterinary student; however, it does contain much of interest to the practicing veterinarian. In the first part of the book clinical diagnostic methods are considered in connection with each system of the body, but the subject matter is treated with such generality and brevity that it loses interest. Each of these chapters is introduced by a very brief discussion of the regional anatomy, but unfortunately the influence of differences in anatomy upon diagnostic methods is seldom clearly stated.

Beginning with chapter 13 and continuing through the sections on clinical biochemistry and clinical hematology the approach to the subject is more direct and informative. The drawings taken from x-ray

films are rather simplified diagrams which bear so little resemblance to actual roentgenograms that they have limited instructional value. The anatomic drawings are useful for orientation but contain little detail. The drawings of smears of various bacteria in color on the other hand are attractive and informative. The print is readable and the text contains very few typographical errors.

This book will undoubtedly be of value to the veterinary student who is being introduced to diagnostic methods. He may also find it useful as a reference book after graduation.

—THOMAS C. JONES Lt Col. V.C. USA

**VIRUS DISEASES AND THE CARDIOVASCULAR SYSTEM** A Survey by Ernest Lyon M.D. 215 pages Grune & Stratton Inc. New York N.Y. 1956. Price \$5.75

In this scholarly book the author has admirably provided a comprehensive survey on the virus diseases and their cardiovascular manifestations. The book is well arranged. A fine foundation is provided by a chapter on viruses in general and associated cardiovascular involvement and a chapter on present cardiovascular concepts of virus diseases. The known viral diseases plus diseases of uncertain but possible viral etiology are developed in detail. Rickettsial infections are discussed with special reference to the cardiovascular system.

The book reflects the tremendous experience of the author who is to be congratulated on his adept manner in which he presents an exhaustive amount of material weaving in his experience and interpretation so that the wealth of reference data flows smoothly and with purpose.

Throughout this volume one is impressed with the basic importance of the capillary syndrome with resulting hypovolemia and its effect on the whole body. The importance of treatment with plasma expanders is stressed. The possibility of cardiac catastrophes as well as prolonged debility and convalescence in some of the viral diseases becomes apparent.

This book is not only valuable for its elucidation on cardiovascular manifestations but also for the fine review of the basic pathology and pertinent clinical data on virus diseases in general and their effect on the human being. It will be of interest to all who work in the field of virology and to internists and is a "must" for the cardiologist. Any reader will find a tremendous reward for his time and will gain a vast store of useful knowledge. An extensive bibliography follows each chapter adding much to its value for reference material.

## Monthly Message

I have recently read the book, *Social Science in Medicine*, by Leo W. Simmons, Professor of Sociology Yale University, and Harold G. Wolff Professor of Medicine (Neurology), Cornell University Medical College, published by the Russell Sage Foundation in 1964. I commend it to all of you.

In the chapter dealing with "Hospital Practice and Social Science Perspective," there is this statement:

We are now ready to conclude that medicine is potentially a social as well as a physical science and that successful medical practice depends on the former as on the latter disciplines.

Although applicable to all of us in medicine this becomes especially important for you who are with the Armed Forces where the problems dealing with sociology, social science, disrupted backgrounds and traditions, and new environments and social groups have a profound effect upon those who come to you for treatment. Frequently these sociological factors may well prove to be the initiating or continuing causes in a physical or organic ailment. Treatment for this latter by itself may be entirely unavailing, or only temporarily helpful unless the total sociological picture is considered. This applies not only to the dependent families but also to the members of the Armed Forces themselves.

These outside factors of social group and environment may play important roles in the health and behavior of the individual soldier, sailor, or airman as regards his daily life, in sudden changes in his action, or as to causation of serious or even fatal accidents.

## Foreword

The United States Armed Forces Medical Journal is the medium for disseminating information of administrative and professional interest to all medical personnel of the Department of Defense. The Assistant Secretary of Defense (Health and Medical) and the Surgeons General of the several services invite all medical officers, dental officers, Medical Service Corps officers, Nurse Corps officers and officers of the Veterinary Corps of the Armed Forces and the medical consultants of the Army, Navy and Air Force to submit manuscripts for publication in this Journal.

## DOCTOR SAMUEL ADAMS

Revolutionary Army Surgeon and Orlarist

THOMAS M HUNTER P A D

**S**AM ADAMS, of Boston Tea Party fame, has long obscured another Sam Adams who, besides being almost as intimately connected with Revolutionary politics as his illustrious kin, was equally as dedicated to the struggling American medical science. This is Dr Samuel Adams (1745-1819) who was born in Connecticut but who lived most of his life in Massachusetts and Maine. His autographed manuscript diary, 1758-1819, in the Manuscript Division of the New York Public Library,\* is probably the most important and extensive medical diary extant of the 18th century and the beginning of the 19th in the United States. Adams started his diary with his *Puerile Diary* on 12 March 1758, at Killingly, Conn., at the age of 13 and ended it on 24 February 1819, at Bath, Maine, at the age of 74.

From History Department Pottsville Center Pennsylvania State University Pottsville Pa

Besides the Samuel Adams diary in the New York Public Library there are a few other known Adams papers. The Massachusetts Historical Society holds 12 items: 1774-1783 relating to inoculation hospitals; hospital conditions; lists of surgeons in military hospitals; prescriptions and provisions; camp news; and army life. These are mostly in the Artemas Ward, William Heath, J. C. Warren, and Henry Knox papers. The Boston Medical Library has one letter about Adams' daughter Clementine's death on 31 January 1815. The Manuscript Division of the Library of Congress has one item: a letter from Adams to a Mr. Hubbard dated 28 October 1782 concerning an order for vinegar for the hospitals at Boston and vicinity. The notebook *Lying in Cases* by S. A. is in the Historical Library of Maine. The Manuscript Division of the New York Public Library also has the diary of Adams' son John for the years 1797-1800-1805-1808. This consists mostly of entries about the weather, boating trips, and the theater of that day in Boston. The theater entries are interesting and informative about the plays then current in Boston. Like his father, John had a philosophical turn of mind and commented from time to time on the foibles of mankind and the futility of life.

At the end of 1768 Adams compiled a volume of extracts from his diaries of the first 10 years and destroyed the originals. Except for the years 1788 1803 1804 and half of 1789 however the daily entries in the series are present from 1768 to 1819. On almost every title page (fig 1) he professed to intend the diary only for his own use. He wrote about 1 000 000 words on more than 3 000 small octavo pages.\*

Nevertheless as extensive and as varied and colorful as the diary is it is apparently relatively little known. Quite possible however Adams painfully diminutive and sometimes obscure handwriting plus occasional code simple though it is would overawe even the most interested reader.

Samuel Adams' quest for professional growth in a then limited science happened to coincide with the troubled Revolutionary period. He started his life and career at the end of a transitional period in both the medical profession and colonial life. After a period in new England when the clergy ministered to the bodily as well as the spiritual needs of their parishioners prescribing mustard or hell fire as the case required,<sup>1</sup> and when frequently the most able medical men were newcomers from Europe rather than American born physicians were coming to regard their practice as a profession in itself. John Mitchell Royal Society William Douglass Leiden and Paris and Cadwallader Colden Edinburgh all European born had already distinguished themselves. Jared Eliot and Zabdiel Boyleston native-born were rising to prominence.<sup>2</sup>

The status of medicine in America in Adams' time was far below that of the science in Europe. The usual method of securing a medical education was by apprenticeship to a practicing physician. Boys from 14 to 17 might serve an apprenticeship of 4 to 7 years. Even those of good family had to do all kinds of manual work besides and as in Adams' case to tend the apothecary shop which was quite frequently an adjunct of the doctor's office. The centers of medical education were Leiden Paris and Edinburgh. The first American to take his medical degree in Europe was William Ball of South Carolina in 1734.<sup>3</sup> The medical department of the University of Pennsylvania was not founded until 1765 the Massachusetts Medical College (Harvard) in 1782.<sup>4</sup> Dissections were scarcely performed in the colonies before 1760 and then by stealth. There were few hospitals. There was the Pennsylvania Hospital founded in 1755 through the efforts of Dr Thomas Bond Sr and Benjamin Franklin and one

in New York in 1771 destroyed by fire and rebuilt in 1774 but mostly used for barracks purposes. Obstetrics in which Adams took a keen interest did not become a part of the doctor's studies until after the middle of the century. Midwifery was completely a woman's domain.

While Samuel Adams did not embody the 17th and early 18th century concept of the doctor combining his practice with diverse other occupations at one time or another he was not only a country practitioner and Army surgeon but a teacher and tavern keeper as well. His commentaries are many, varied and rich. His record is extensive and diverse. In this respect, he deserves to be ranked with his more famous Adams kin whose diaries are so currently newsworthy.

In the common practice of the day Samuel Adams also sought to set down in his *Anatomy and Commonplace Book* all of the knowledge obtainable in his day. He was an avid collector as well of medical recipes. He seems in fact, to have recorded every conceivable kind of sense or nonsense. Even considering some of the fantastic compounds in use in his day and it must be remembered that the 16th century was no such an age of quackery as of reason. Adams must have had doubts as to the efficacy of some of the proposed remedies. Many of these miscellaneous and questionable and anything but scientific medical recipes were simply taken from an old *Anatomy and Commonplace Book* of Dr. David Sharrows. We must remember too that medical concepts of that day were based on a melange of ancient belief founded in magic and religion, hidebound tradition and doctrines which were formulated by authorities over the centuries and accepted more for that reason than through any scientific testing. A typical recipe is "Good dung mingled with vinegar and a little bran and applied as a plaister to a sore breast catcheth wonder fully all swellings thereof." We need not wonder so much at this however for though earlier William Penn certainly a highly intelligent man had included in his book of *Physick* a terrific concoction of butter, black snails, rosemary, lavender, elder new cow dung and new hen dung for bruises. A remedy for hiccupps was "Stop both your ears with your fingers and the hiccough will go away." For ringworms the prescription was "Take Vitriol all two drachms and dissolve it in a pint of clear water and with the water wash the hands it will cure ringworms better & scales in the same." To test fertility "Let a woman make water in a urinal that is cleann upon some barley corns and set the same in a cold place 8 days and if the [illegible] barley corns will grow again then the fault is not in the woman that she conceives not but in the man if otherwise than the fault is in her."

There was a liberal mixture of astrology also with this kind of medical practice "Let the physician take heed," was the warning, for example, "of his first visiting of the sick in the hour of Saturn and Mars if he come to him in the hour of Saturn either the sick will dye or else the physician shall have great labour doubts & [illegible] in the caring of him if in the hour of Mars there will be chidings and brawlings between him & the sick party & shall gain the hours of Jupiter & Venus are much praised the hours of the other planets are indifferant" One was to be particularly wary of Venus, however, when it came to receiving money, for, "He that receiveth a sum of money in the hour of Venus will spend the same with women in pleasure and wantonness"

Dr Adams also extracted from the manuscript of Dr Nathaniel Freeman, his mentor, who, in turn, had extracted it from an old manuscript of a Dr Cobbs, dated Barnstable, 4 December 1739, the following calendar of medical treatment

January—let not Blood nor physick this month unless some extraordinary occasion require it and beware of taking cold for Rheume and phlegms do much abound this month

February—if Necessity urge you may let Blood but be sparing in physick till March or April

March—now is the time to let Blood and Humours encrease

April—now purge and bleed the pores are yet open let Blood three months the moon being in Cancer or Taures it is Extreame perilous for the moon to be in ye same sign that rules the member in which the vein is opened Best to take purges when the moon is in Cancer Ointments or plaisters best applyed when the moon is in the same sign that rules the member to which it is applyed

May—(blank)

June—(blank)

July—abstain from physick unless Necessity urge

August—observe the same & letting blood

September—is a good time to use physick and phlebotomy as the opening a vein to discharge some of the blood

October—physick is to be used also this month

November—(blank)

December—the best physick this month is wholesome diet warm cloaths good cyder or beer and a carefull loving wife

In allusions to his love affairs and subsequent marriages sometimes by the repetition of certain initials in the lower right corner of his daily diary entry, or an occasional *scandale* in code Samuel Adams' diary is much like that of the famous Samuel Pepys. He appears to have married five times and to have had 15 children. He first married Deborah Larned on 21 March 1764. The first child died of a "Whooping cough" and Mrs. Adams died of "a consumption." Adams next married Abigail Jordan on 19 July 1773. She died on 8 July 1774, in childbirth. On 1 August 1776 he married Sally Preston who died on 24 September 1787 after an extended illness. The *Adams Genealogy* records Samuel Adams' marriage to Abigail Dodge on 29 June 1789. This is perhaps an error in the year, for there is no corresponding diary entry for that date. Abigail also died and Samuel last married Mary Ann Bent on 10 May 1815 at the age of 70 and had one daughter by her.

Samuel Adams was born on 26 January 1745 in Hillingly, Conn. to Michael and Sarah Shuttleworth Adams. His father was a direct descendant of the first Henry Adams who came to America in 1636. At the age of 17, Samuel Adams set out to be a foot soldier. He drew bounty on 11 May and joined Captain Spaulding's company of the regiment of Colonel Phineas Lyman at Plainfield on 19 May. Adams' regimental commander was then gaining a reputation during the Seven Years War, as the most able and trustworthy provincial general throughout the northern colonies and was even approved of by his British superiors at the same time that he was working to maintain the independence of his colony. Dressed in "the finest coat ever seen at New York" he sailed to join Albemarle in the expedition of provincial troops to Havana. The young impressionable Samuel Adams was no doubt greatly influenced in his political views by this able, young patriot. Physically however he suffered badly from the expedition and returned from it in very poor health. It was only during the following year that he recovered his health sufficiently to start studies at Hillingly with Dr. Nathaniel Freeman, another ardent patriot who as Lyman almost lost his life at the hands of Loyalists. Adams left home on 7 December and began his studies at Hillingly in March. Between 26 October and 10 November he studied under a Dr. Ironwood. Then on 12 January 1764, he began teaching school for a Mr. Turner.

On 3 September 1766, Adams went to Sandwich, Mass. located on Cape Cod Bay. Two days later he began the study of Physics under Dr. Freeman. He read a great deal from the works of the celebrated Hermann Boerhaave of Leyden, but he read not in the field of military medicine. There were few books on the subject then available in the colonies, except for the British

authority Sir John Pringle's *Observations on the Diseases of the Army* and the writings of Gerard Van Swieten. Van Swieten was a Viennese professor of surgery who wrote an important work on the hygiene of troops in camp<sup>12</sup> which, in the American edition, first appeared in Philadelphia in 1776, apparently for hasty use by the Revolutionary troops. Dr Freeman served as Adams' mentor and took him along when he visited his patients. Inasmuch as the duties of apothecary and physician were not divided until later decades,<sup>1</sup> the young medical student spent many hours in what appears to have been Dr Freeman's apothecary shop. Here he compounded the popular "potions," "infusions," and "electuaries" of the time.

Young Sam Adams was also being trained in pre Revolutionary politics as well as medicine. His mentor, Freeman, was later persuaded by his great uncle, James Otis, Sr., to read law. Freeman emerged as an able and prominent young patriot and became the moderator in Sandwich town meeting. He moulded patriotic sentiments and restrained the activities of the more spirited of his pro British neighbors.<sup>13</sup> Adams did not study law or become a magistrate, as Freeman, but he otherwise followed suit.

In April 1769, Samuel Adams began the practice of medicine at Truro, Mass., near Cape Cod. He resorted frequently to the common practice of blood letting, extracted teeth on many occasions, and endlessly prescribed cathartics such as sal ammoniac and diaphoretics for fever, elixirs such as antimony for female disorders, and varied tinctures and cordials for the stomach. A typical diary entry is, "September 12, 1769—Fair weather. Visited Mr. Knowles boy who had cut off a finger. Dressed it as a simple wound & extracted a tooth for Mr. J. Athens wife—gave Nitric & Calom to Mr. Nicholson little girl for worms."

Adams' interest in childbirth was lively, and he kept precise accounts. He sought constantly to facilitate rapid delivery. Part of his diary entry of 26 December 1771 is rather illegible, but it shows the care which Adams exercised and the skill which he must have had in child delivery.

was called about sun up to [illegible] in Falmouth in travail with her fifth child arrived about 10 O'clock found (by Mrs [illegible] the mid wife) that she was taken in Labour about [illegible] the membrane broke while she sat before the fire and the waters discharged her pains had been hard but not frequent all night—upon examining I found the os externum and internum fully dilated [illegible] finding the hand without the os internum and the funis umbilicus fallen down behind it the child's hand to the mother's right [illegible] I introduced my left hand the woman lying in a supine position under the arms to the child's [illegible] which with the hand I [illegible] as much as I could to the

[illegible] for the feet which not without difficulty I brought down to the os internum then introducing my other hand and around [illegible] the head—while with my left hand I gently pulled the feet and to my joy the arm extended into the [illegible] I then waited for a Labour pain which forced down the child with the hips without the os extermum & finding the pains did not force enough to bring the child without bringing down the arms I introduced my finger and brought them down over it [illegible] minding to turn the forehead into the hollow of the sacrum and putting my finger into the mouth brought out the head with a [illegible] it was a very large girl [illegible] woman comfortable—the operation lasted 40 minutes

In Ipswich between 1782 and 1796 Adams attended 485 women in childbirth and never once used the forceps, nor did he lose a single mother. From the time that he moved to Bath Maine in 1796 until his death in 1819 he attended an additional 1115 deliveries. He recorded all of these cases between 1782 and 1819 in his extensive notebook *Lying in Cases by S. A.*,\*—briefly usually, but always plainly. He was ready to go almost anywhere. There were instances of births at the Isles of Shoals off Ports mouth and Wood Island at the mouth of the Merrimack.

Sometimes he was called so late that the patient was close to being in extremis. He reported an earlier case, on 27 May 1772 of an expectant mother who had been in strong convulsions for some time and who died after Adams had delivered a live baby. When first saw her every symptom seemed to indicate that she was

ying. He supposed the woman to be about seven months gone with child. "Let her bleed," he says "ordered a clyster—gave nervous medicine and an opiate but gave no relief—introduced hand in uterus. Shoved up the child's head brought down the feet and delivered with care a fine girl alive."

Adams was called upon for his obstetrical services by people far and wide. He attended the wives of Dr. Nathaniel Weld and Dr. Timothy Waldron of Bath. There are few other traces in Maine medical history to be found of these cases. Little otherwise is known of some cases, however, for according to his *Lying in Cases*, Adams kept a separate account in great detail of his most difficult obstetrical cases but though the search has been intensive this second notebook has never been found. In the first notebook he told of his meeting his own fourth wife who had brought into the world 14 children. Of his own children he never mentioned more than eight from four wives. In his practice twins were not uncommon. Occasionally labor was tedious but usually

In the Historical Library of the U. S. Army Medical Department, Washington, D. C. is a copy of the original manuscript of this paper, which was written by Dr. Adams in 1819. It is a very interesting and valuable document, and is a good example of the work of a pioneer obstetrician. The paper is written in Adams' own hand, and is a very good example of his style of writing. It is a very interesting and valuable document, and is a good example of the work of a pioneer obstetrician. The paper is written in Adams' own hand, and is a very good example of his style of writing. It is a very interesting and valuable document, and is a good example of the work of a pioneer obstetrician.

it was rapid. Although often short, the umbilical cord was more often very long. Frequently, and in curious manner, it was convoluted around the neck, body, and arms. Adams noted the cases of two children born with six fingers and toes on each hand and foot. On others, there were a few instances of supernumerary fingers. Infants weighed from three pounds to eleven and three quarters. In a case of eclampsia with convulsions, Adams noted that, "All the women in the room and house were frightened at nothing," but that he finally brought the patient around all right by giving opium abundantly. Many times at the end of a delivery, Adams would add "Went home at last, mother and baby doing well." He did most of the midwifery in Bnth for many years. He had one rival, an Old Granny Lombard, who for a silver cart wheel (silver dollar) would bring an infant into the world. She had enough common sense, though, to know just when to get her dollar, then to give Dr. Adams a chance to earn his five and travel costs and to finish the case properly. On more than one occasion, Adams had incognito patients as private boarders in his home. One time, he carried the child in the night to elsewhere in the community to be suckled for five shillings per week.

By 1770, Adams was becoming involved more deeply in pro Revolutionary politics. He was a dedicated patriot. While at Truro, he was quite active in controlling the few Tories of the neighborhood. He recorded the Boston "Massacre" on 16 March 1770 as follows: "Fair Dressed foot wound Received News papers on account of the unhappy affair with the soldiers. Vid B Gazette March 12, 1770." He attended annual commemorative services for this occasion in later years. On 1 June 1774, he bitterly described the blockade of Boston Harbor (fig. 2).

On 2 July, Adams' first son was born but died on the last day of the month. He described his wife's sickness and death with agonizing detail from 3-8 July.

By fall, stirring meetings were being held about Tea and Tories, and Adams was sometimes the clerk. On 22 October 1774, Adams recorded "S. Cloudy somewhat. Went to Captain Jonathan [illegible] Freeman's & to sundry other places among the shops. Died this morning Mr. William Mollineaux greatly lamented by the Whigs but to the joy of the Tories." He attended the Mollineaux funeral on 24 October and the next day visited Faneuil Hall for a town meeting. He saw General Gage and noted that, "Gen. Gage has nothing majestic or thinking in his person. His person does not bespeak him capable of the great business he is bent upon."

Adams' mentor, Dr. Freeman, now suggested that Adams apply for a warrant of surgeon. In the spring of 1775, Adams visited the army at Cambridge and saw General Washington, with whom he

was frequently in company Inter He recorded the battle of Bunker Hill on 17 June On 7 July, a board of surgeons appointed by Congress and consisting of Drs Benjamin Church, John Taylor, David Jones, William Whiting, William Bayless, Jeromiah Hall, William Dinsmore, and Samuel Holten\* examined Adams and gave him a warrant of surgeon the following day Adams could be called "Mister" or "Doctor," but there was no rank with his commission. He was assigned to the 18th Regiment of Continental Infantry<sup>11</sup> under Colonel Edmund Phinney at Roxbury He served from 1 January to 31 December 1776 \*\*

The news of the evacuation of Boston by the British army was music to Adams' ears On 17 March 1776, he wrote

The British army in Boston under General Howe consisting of upward of 7000 men after suffering an ignominious blockade for many months past this day disgracefully quitted their Strong holds in Boston & Charlestown and precipately fled from before the Army of the United Colonies & took refuge aboard their Ships—a detachment of our Army under Genl Putnam took possession of the Town of Boston with all its important Posts in the name of ye 13 United Colonies of North America—another detachment of Bunker Hill

In April, the smallpox broke out in the army and became epidemic On 17 July 1776, Adams wrote, "Came into town in the morning—found the town under inoculation about 8000 persons having received the small pox in that way" Even several months previously he had mentioned sending various men to the small pox hospital at Howell's point He also recorded a number of private inoculations, some in code, as 10 April 1776 "D4ct SpglO 1384156H2d pg3vite6y f49 thz Sml86 p4x [Doctor Spiro inoculated privately for the small pox]" The descriptive material with the Adams diary states that Adams confirms the report which was circulated that the British had sent an infected Indian to Boston to spread the smallpox, but, after an exhaustive search, I have not been able to find such a specific diary entry Assuming that such a report was circulated, Adams possibly gives some credence to the report when he says on 27 July, "An Indian fellow died with small pox" Whatever may be the facts of the story about the infected Indian, smallpox was a scourge to the health

---

Adams just mentions Drs Church Taylor Jones and Holten and the committee appointed by Congress The complete names of these doctors and those of the committee members have been taken from Duncan's Appendix B List of Medical Men Who Took a Part in the American Revolution pp 379 414 and p 40 for the examining committee

\*A diary title page of Adams' mentions service under a Colonel Fellows before Boston in 1775 This is not listed in the Surgeon General's Records<sup>11</sup> as official service and must have been before Adams was given a warrant of surgeon by Congress

and morale of the army. It was even more destructive than British bullets during the first two years of the war.<sup>12</sup> It has been said however that there was little suffering at Boston, this in spite of the fact that Dr. John Morgan was opposed to inoculation.<sup>13</sup> The little suffering was probably due, therefore, to the systematic efforts of medical men such as Adams who believed that inoculation, "heroic" weapon though it was, would prove to be effective. During the summer of 1776, it was generally being applied. Washington is said to have been inoculated.<sup>14</sup> Adams not only mentions the inoculation hospitals in his diary, but there are two letters in the Dr. Samuel Adams papers of the Massachusetts Historical Society which relate to the establishing of inoculation hospitals.

From these concerns, Adams now momentarily turned to marry again. He married Sally Preston on 1 August, but he was soon back with the army. Seven days later he marched with his regiment to Ticonderoga. Supplies were frequently short, but, on 7 September, they finally reached the fort. Six days later he reported the battle on Lake Champlain. He was kept busy with the sick and the wounded from the battle of 13 October. He recorded in his diary the loss of the Royal Savage. On 23 November he set out for Lake George.

Adams participated both in the campaigns in New York and New Jersey and in December 1776 he transported the sick to Albany and received a leave of absence. Everywhere he went he noted the customs and habits of the people. He was no doubt already familiar with the beadle in early churches who carried the collection bag on a large pole, but when he visited the Dutch church at Albany and saw the collection bag on a stick with bells, he thought that it was worth recording in his diary.

From time to time Adams went on leave from the army to visit his family or to move their residence. Wherever he was, though he showed his endless curiosity. On 9 January he wrote "some what cloudy but not so as to hinder seeing the Eclipse of the Sun." Between 15 February 1777 he moved his residence from Truro to Dorchester, south of Boston.

During 1778 Adams was frequently on the move. He took the time however on 3 January 1778 to dissect a dog, but he tells nothing more of it than just that. On 17 March 1778 he recorded "Cold with some squall of snow. Dined at his Excellency Gen. Washington's headquarters Middle Brooke." On 14 May he joined the 3d Continental Artillery Regiment<sup>15</sup> under the command of Colonel John Crane. The colorful Crane, one of the Sons of Liberty, had also been one of the Boston Tea Party Indians. While down in the hold of one of the ships he had been knocked senseless by a chest of tea. His companions believing him

dead, had concolod him under a pile of shavings in a nearby carpenter shop Crno had a sturdy constitution, though, and rocovered On 1 January 1777, he had taken command of the 3d Artillery Regiment which served ns a detachment under Sullivan in the Rhode Island campaign Ho received honorable mention under Gntes nt Saratoga and in the defense of Red Bank.

In June, Adams journeyed into the Pennsylvannin German country He visited Bethlehem and wrote in his diary about the customs and habits of the Moravians He was especially impressed by their quiet and civil manners, their ingenuity, industriousness, and thrift

This was just an interlude, however, because of the rapid acceleration of military movements On 5 June Adams marched to Morristown On 17 June he wrote, "Air very hot Crossed Sullivan's Bridge over Schuylkill and got into camp at Valley Forge about 10 o'clock Dined at Gen'l Knox's " Ho reported the engagement at Monmouth and had the care of the sick at English town "Our army," he says on 29 June, "after burying the Dead, taking care of the wounded we left nt night marched back to Englishtown I went over the field of battle A shocking sight!" On 13 July he assisted Dr Charles McKnight,\* a New York surgeon, in snwing off part of the fibula of Captain Thomas Arnold's leg and later helped Dr McKnight to amputate it "The ball," he said, "was ledged in the center of the tibia, which bone was fractured badly " All compound fractures at that time, except those of the hip joint, called for amputation, and Adams concluded that there was no possibility of saving the leg Ho thought, in fact, it a pity that this had not been recognized and the leg amputated before

During 1779, there was a period of relative quiet and inactivity in Adam's service When he was not attending the sick, he spent much time in reading in bed, which was the warmest spot in a room without a fire Ho played a lot of backgammon which he called the "ministerial game of Back gammon" On 6 August he visited the artillery and found them afflicted with nothing more serious than bugs The report of this, which soon made the rounds of the camp, and which Adams recorded in his diary in code, provided much merriment to a dull camp life

The years of 1779 1780 were bitter, frustrating ones for Adams He no longer wrote of "the brave and worthy Bostonians " He now referred to them as "smug Bostonians " As many army men,

---

Adams only mentions a Dr McKnight This could only have been Dr Charles McKnight because he was the only medical man by that name in the American Revolution

Adams had received little or no pay He engaged in constant wrangling with the legislature for back pay The currency was depreciated Prices were skyrocketing A pound of butter was a dollar A hat sold for as much as \$1 000 and Adams paid \$250 00 per week for board for himself and his family Adams was progressively becoming disillusioned

On 9 April 1780 he received a leave of 60 days He was in desperate financial circumstances By 24 April 1780 Adams let himself go in a tirade against his previously "brave and worthy Bostonians" He wrote in his diary 24 April 1780 Went to Boston with Mrs A—went to a great number of places on business—the currency depreciated to almost nothing—it seems to me the people are all mad—would to God they were all obliged to serve in the army as private soldiers one winter and farc as the troops did last winter in West Point—it might I think bring them to reason "Two days later, he continued This day by order of Congress observed as a day of fasting and prayer throughout the united States—could not attend Meeting for want of cloaths to appear decent—brought to this in the service of my country!"

Adams' bad temper about the especially seamy sides of the war was temporarily mollified during 1780 and 1781 possibly partly because of his being made a hospital physician and surgeon on 6 October 1780 and partly because of his intimacy and conviviality with Washington Lafayette and other high ranking persons On 26 December 1780 he wrote "Dined at his Excellency Genl Washington with Genl Howe, Col Scherrel, Doct Cochran—good dinner—excellent glass of wine—very agreeable company—spent evening in reading in the Boston Chronicle for 1767" Yet the instinctive bitterness remained and soon cropped up again On 1 January 1781 General Knox entertained all officers of the Brigade at dinner "We were a set of poor miserable boys without a single shilling in our pockets—consider this ye money catchers at home and think what you deserve for your sordid avarice and your treatment of your army"

By 5 February, Adams' drooping spirits revived again On that day he wrote "Cleared away last night—fair day—much warmer than yesterday—walked to the Park exceeding bad walking visited my Patients all doing cleverly—Dined at Head Quarters New Windsor—Marquis de La Fayette General Clinton also there—exceeding good dinner—Wino excellent' enjoyed myself well—Miss Hamilton present pretty little Brunette much fine in her eye "This camaraderie had its effect While he deplored the general attitude of the public Adams held his respect for the leaders of the army He later named a son for Henry Knox, general of the artillery command under which he served During

August 1781, he was received again by General Knox "Waited on Genl Knox," he wrote, "was received cordially as I could wish for"

Disillusioned as he was, Adams did not resort to corresponding with the enemy as Benedict Arnold. Adams rather fully relates the news of Arnold's treason in 1780, and he was completely unable to understand how Arnold, after having served his country with a bravery that bordered on madness, could now turn to the enemy. He concluded that "an incurable thirst for gold" was the only thing that "would [have] induce[d] him to overturn that cause in which he had fought so bravely!"

Adams had been granted a 70 day leave of absence on 21 February 1781. There was a growing doubt in his mind that he should remain in the army. He took to lobbying while attempting to get his back pay from the government. Apparently it was necessary to get a petition through the legislative houses before payment could be made. Adams' petition passed one house, but failed in the other. He was enraged to the breaking point and wrote in his diary, "I had the satisfaction to speak my mind freely on the affair and among many other things I told several of the Senators before a number of witnesses on the floor of the State House that what they had done was worse than High way Robbery—which they swallowed tolerably easy—oh! the Brutes!—stupid low liv'd Devils!" By August, Adams was thoroughly discontented and tired of war. Between 22-27 August, he was at Verplanck's Point and West Point. On 4 September, he noted in his diary that he was even unable to pay the postage on a letter from his wife.

The war news gave a lift now, however, to Adams' shattered morals. On 24 September 1781, he recorded, "A report prevailed yesterday and this day that in an action between the British and French fleets off the Chesapeake, the latter were completely victorious, that the British had two ships fired three run aground and four taken—that this has caused the greatest consternation in New York, and that they are preparing to evacuate it—a glorious affair. God grant it may prove true and that this campaign may be the last of the war." "The tide of victory was turning quickly now, and, on 28 October Adams wrote, "Authentic intelligence arrived here this evening that on the 19th inst. two of the enemies redoubts at York Town were stormed one by the French the other by the Americans and carried with little loss, that hostilities ceased on the 19th and on the morning of the 19th Lord Cornwallis marched out with his army when 3400 reg. troops grounded their arms, 2000 more were sick & wounded in the hospitals."

Shortly thereafter, Adams became ill. He secured a leave of absence from 6 December to early April and returned to his family.

on 15 December. He set up housekeeping in Boston, undoubtedly with a view to keeping an eye further on the legislature. On 11 July 1783 he resigned his commission.

During this time besides trying desperately to get his back pay, Adams looked about for a town in which to resume private practice. A Dr Manning, probably John Manning, an Army surgeon of Massachusetts proposed a partnership in Boston to Adams. Adams rejected it. Instead, he removed to Ipswich, in northeastern Massachusetts to continue private practice.

Samuel Adams' diverse interests never failed him. He entertained President Washington on his passage through Ipswich on 30 October 1769. On 20 December he was in Boston and went aboard the new India ship of 800 tons built at Braintree for Shaw and Randall to be used in the Canton trade.

The immediate years which followed were seemingly rather quiet ones so far as the practice of medicine was concerned and Adams turned to tavern keeping for several years. In 1792, he leased Treadwell's tavern house for three years from 1 May at 45 pounds per year. On 19 April, he also agreed to attend the poor of the town for 25 pounds and 15 shillings. He commenced tavern keeping on 10 May, but it does not appear to have been rewarding in any particular sense unless it was the satisfaction which Adams undoubtedly received from the atmosphere of a public house.

At some point during these years Adams decided to journey to Maine with a view to moving there. General Knox, Colonel Plummer and other military officers of his acquaintance seem to have urged and advised him to do so. They knew that he was unusually capable and might find more opportunities for advancement there. It is also possible that Mrs. Adams helped to prompt him inasmuch as she was from Portland. Between 29 February and 1 May 1796 he journeyed to Maine and rented a house at Bath for \$40 per year. He sailed with his family for Bath on 6 July. In 1799 he was said to be living on Washington Street.

Samuel Adams spent the rest of his life in country medical practice. He was the only physician in Bath. The next physician Dr John Stockbridge did not settle in Bath until 1813.<sup>1</sup> Adams wrote in his diary about family life, current events, social affairs, his medical practice, work in the kitchen garden, now his main hobby and his fondest and, finally, the weather. His

Letter from Mr. Henry W. Owen to the author of *The Edward Clarence Plummer History of Bath, Maine*, 14 May 18 1956. Mr. Owen says Dr. Adams resided at Levi P. Lemont's residence on Washington Street in 1799.

lifelong interest. On 7 January 1800, he took part in a procession in memory of George Washington. He was one of the contributors to the fund for the purchase by the North Church in 1803 of the Paul Revere bell. The bell now hangs in the belfry of the Bath City Hall. On 2 February 1804, he was made a fellow of the Massachusetts Medical Society. He was active in Masonic affairs, being a charter member of the Solar Masons, F & A M, founded in Bath in 1804. In 1805-1806, he was its second master, succeeding General William "Sultan" King, a wealthy shipowner and the first governor of Maine. Although the records are fragmentary, Adams was paid by the town of Bath in 1811-1812 to be in attendance upon the poor. He was also one of several gentlemen who were incorporated by the General Court under the title of Trustees of Bath Academy. This was the Female Academy which later became Bath High School.

Age was no barrier to Adams' interest in portraiture and family life. After the loss of his fourth wife and children Albert and Clementine during these years, at the age of 70, he married Mary Ann Bent by whom he had a daughter Julia Ann. On 21 November 1816, he had his likeness made by Benjamin Greenleaf,\* the popular but rather peculiar portrait painter, educator, and author of important mathematical textbooks. Greenleaf lived with the Adams family. Adams wrote in his diary, "I had my likeness taken by a Mr Greenleaf who came to our house on Monday last." Greenleaf, as was the custom of the times among artists, was no doubt off on a rambling itinerary of portrait painting. Just what he received as remuneration for his portrait of Samuel Adams is hard to say, but Adams was determined to get his board money. He wrote on 14 December, "Mr B Greenleaf board settled up to this day—balance of all accounts Board begins anew from this morning."

Samuel Adams' diary entries were gradually tapering off. In October 1817, he visited friends and relatives in Boston, Andover, and Ipswich. His daughter Julia Ann was born on 13 June 1818. On 25 February 1819, he characteristically but symbolically wrote the last entry in his diary. "Cloudy," he wrote. Nine days later, Dr Samuel Adams was dead.

\* See footnote on p. 640.

This Greenleaf portrait may no longer be in existence. It is not listed with known Greenleaf portraits (reference 1440 *Early American Portrait Artists 1663-1860*, preliminary volume compiled by The New Jersey Historical Records Survey Project, CPA, Newark, N. J. The Historical Records Survey, 1940) and an extensive search by the author has produced no lead as to its existence or location. It may have been lost by being broken. This is what happened in at least one known instance and is unfortunate because Greenleaf was an accomplished limner on glass. He is said to have lived in Phippsburg down the river from Bath, Maine, 1810-1817 according to a letter from Carl N. Schmalz, Jr., Curator of Bowdoin College Museum of Fine Arts, July 10, 1956.

Samuel Adams was a physician when earnest efforts were being made to strengthen the scientific basis of medicine. He is said to have been "the most intelligent and successful practitioner in the state of Maine" in his day. This is probably true. He was undoubtedly highly regarded in Massachusetts as well. It was not an easy time, however, in which to grow professionally. Beneath the troubled political events of the Revolutionary era, America was experiencing a cultural undercurrent. It no doubt even helped to mould the political events, but political nationalism took precedence over cultural nationalism. The physician nevertheless was emerging as a professional man, and his social standing in the community depended largely upon his medical success. In his time and place, Samuel Adams was a success.

The era of Samuel Adams was a transitional one, and much yet remains to be known about it. Samuel Adams did not achieve eminence as say John Morgan, Edward Shippen, or Benjamin Rush of the Revolutionary generation. He was in many ways though more fortunate than they. He did not become involved in the violent medico-political conflicts of the day as they. Adams' diary simply reveals the life and work of a physician of varied interests and inquiring mind who tried especially to improve obstetric procedures before there was even such a phase of medical study. As an Army surgeon, he gave some of the best years of his life to the service of his country. As a hospital surgeon, he sought to improve hospital facilities and administration. It was a day when medical men had too few facts with which to work. They tried nevertheless to apply logic to what facts they did have. Tentative as much of it was, an increasing pursuit of science was going on in America. This growing interest in science and its influence upon Revolutionary America and subsequent history is only now coming to be known. Samuel Adams belongs to that formative period in American history.

# THE ROENTGEN DEMONSTRATION OF DUODENAL ULCER

EDWARD R. HEITZMAN, Jr. *Captain USAF (MC)*

**R**ECENT reviews concerning the military effectiveness of ulcer patients made by Palmer, Sullivan, and Hamilton<sup>1</sup> indicate that the problem of duodenal ulcer in the armed services is one of greatest importance. The age incidence of duodenal ulcer and the fact that it is four times as common among males as among females predisposes military populations to this disease. Sherman's<sup>2</sup> recent article concisely summarizes some of the important points that indicate the magnitude of the ulcer problem. He emphasized the high incidence of ulcer and the fact that this incidence is increasing. He also pointed out the extensive morbidity and the significant mortality arising from this disease. The number of man hours lost due to ulcer is overwhelming. The possibility of sudden perforation, hemorrhage, et cetera, is always present and among key personnel particularly those who fly may result in tragic accidents.

In many instances the diagnosis of duodenal ulcer can be made with assurance from clinical symptoms and findings alone. Many times, however, the presenting complaints are bizarre. Several other conditions may simulate the ulcer syndrome closely. Indeed, some of those individuals with the most typical ulcer syndrome subsequently are shown to be suffering from a condition other than ulcer. Many times the distinction between gastric ulcer and duodenal ulcer cannot be made clinically, yet this is an absolute necessity because the course of each disease is so different.

Most of the upper gastro-intestinal series on military personnel are performed with the differential diagnosis of ulcer in mind. It therefore, seems obvious that the examination of the upper gastrointestinal tract for ulcer must be regarded as an examination of utmost importance. Hodges has emphasized this by stating "Haphazard superficial or careless examination of patients has no place in the search for these lesions and can do much harm by providing erroneous opinions in whichever direction the error is made. An incorrect diagnosis of duodenal ulcer may sentence a patient to . . .

prolonged period of unnecessary irritation and restricted opportunity in life. Failure to recognize the lesion when present provokes a false sense of security which may well be fully interpreted by the totally unexpected development of one or another of the common and frequently tragic complications of the disease. Actually, an expert examination is less than valuable, it is an unnecessary imposition upon trusting patients.<sup>21</sup>

Nevertheless, despite the most skilled examination of the upper gastro-intestinal tract, it is stated by many authors that evidence of duodenal ulcer can be found in only 50 to 60 per cent of patients with an actual ulcer. Bockus<sup>2</sup> believes that, if one included all types of duodenal deformities and mucosal defects, approximately 90 per cent of ulcers would be revealed by roentgenographic examination. It seems worthwhile therefore to review the primary and secondary findings in duodenal ulcer and to emphasize certain techniques by which ulcer may be diagnosed with greater accuracy. In this review, pyloric ulcer and post-bulbar ulcer are excluded as constituting special problems. However, most of the subsequent statements apply equally well to these lesions.

It is hoped that these points will be of some interest to those doing radiologic work in the armed services where, due to the relative shortage of radiologists, some roentgenographic examinations must, of necessity, be done by general medical officers with a limited background in radiologic technique and experience.

### ROENTGEN SIGNS OF DUODENAL ULCER

Correlation of radiographic findings in duodenal ulcer with gross and microscopic pathologic findings is difficult to obtain because many patients with duodenal ulcer are never operated on. In fact, many of the patients operated on have subtotal gastrectomy performed without excision of the duodenal ulcer. In many cases technical difficulties preclude an accurate visual examination of the region of the duodenal bulb at operation. Nevertheless, over the years certain types of roentgenologic findings have become relatively well standardized and can be relied on with considerable certainty.<sup>22-24</sup>

It should be emphasized that active duodenal ulcer can be diagnosed with 100 per cent certainty only when the actual crater is demonstrated. This is the only sign pathognomonic of ulcer. It has been stated that an attempt should be made to visualize the ulcer crater *en face* and in profile on every examination (fig. 1). Frequently this is not possible, and a clear cut demonstration of the crater in either of these two projections is sufficient to make a definite diagnosis.

When an actual crater cannot be demonstrated, the diagnosis of an active duodenal ulcer can often be made accurately on the basis of

basis of so-called secondary signs. These secondary signs may be grouped into findings indicative of consistent bulb deformity and findings indicative of bulb irritability or spasm, bulb tenderness and secondary gastric changes.

Figure 1 Ulcer crater or niche on the anterior wall seen en face (left) and in profile (right).

Deformities of the duodenal bulb may take many forms. Among these are the so-called half bulb deformity, fir tree deformity and the mid bulb constriction referred to as the clover leaf or necktie deformity. Other significant deformities are the incisura, radiating folds, microbulbus, prestenotic diverticulum, eccentric pylorus, et cetera (fig. 2). These deformities appear to be the result of mucosal edema coupled with a certain amount of muscular spasm within the duodenal cap. Fibrosis may play a role in lesions of longer standing, and some of the more chronic deformities may be due to periduodenal adhesions. Under certain circumstances any of these findings may be present in a chronically scarred bulb in which no active ulceration is present. However, any of the bulb deformities should, when found, indicate a very careful examination in a search for the actual ulcer crater. If a crater cannot be demonstrated, the evaluation of irritability or spasm of the duodenal bulb becomes of importance in indicating whether an active inflammatory process is present.

Evidence of spasm or irritability will be noted only on careful and relatively prolonged visualization of the duodenal bulb. If the duodenal bulb never fills out well during the period of observation and passes barium through at a very rapid rate, some spasm may be inferred, although some exceptions to this statement will be encountered. Spasm of the pylorus is a frequently encountered problem and is not necessarily indicative of a pathologic condition in the duodenum. Various maneuvers may be carried out in order to relieve the pylorospasm. The greatest success in over

May 1957

coming it has resulted from placing the patient on the right side for a few moments. Occasionally it is necessary to discontinue the examination for a period of several minutes. When pylorospasm is present duodenal ulcer should be suspected. Bockus stated that actual hypertrophy of pyloric muscle is seen in duodenal ulcer. Without other corroborative evidence, however, pylorospasm is a nondiagnostic finding because it can be found in many subjects without organic gastro-intestinal lesions. Certain drugs have sometimes been administered to overcome pylorospasm but this is very rarely necessary.

Careful palpation should always be carried out in an effort to elicit consistent tenderness in the region of the duodenal cap. Active ulceration within the duodenal cap may be suspected if consistent tenderness in the region of the bulb is elicited during palpation in various positions. Certain patients may fail to admit pain even when it is present because they realize that loss of job opportunity or other adverse circumstances may result from the establishment of an ulcer diagnosis. This is particularly true among those who fly since the establishment of a definite ulcer diagnosis may result in the loss of flying status. However even consistent tenderness is of little significance unless correlated with other roentgenographic evidence.

The gastric signs of duodenal ulcer have been referred to by many authors. Essentially these are hyperperistalsis and prominent mucosal pattern with or without gastric retention. The presence of retained food or fluid within the stomach accompanied by some gastric dilatation is indicative of outlet obstruction of the stomach which in the absence of an antral lesion is statistically most likely to be due to a partially obstructing duodenal ulcer.

It is clear that evaluation of these so-called secondary signs of duodenal ulcer requires considerable judgment and experience and is fraught with pitfalls. It is the proper assessment of these signs, however, which must be sought in an effort to increase accuracy in the roentgenographic demonstration of this disease.

It is always unwise to make a definitive diagnosis on the basis of physical findings without obtaining a detailed history. Similarly, the radiologist should be fully informed of the patient's history prior to the roentgenographic examination. An adequate history should accompany the request for the examination and the radiologist should interrogate the patient in an effort to obtain correlation of clinical evidence and roentgenographic findings which will lead to the highest degree of diagnostic accuracy.

There is a condition which is perhaps overdiagnosed and controversial but has been definitely shown by Kirklin to be a clinical and pathologic entity. We refer to duodenitis of the duo-

denal bulb. This requires special consideration. It is not possible to give an absolute roentgenographic diagnosis of duodenitis without perfectly typical findings correlated with typical symptoms and clinical findings. This is particularly true since normal variations in the mucosal pattern of the duodenal cap may in certain extreme instances simulate the pattern seen in duodenitis. These findings are usually described as a small bulb presenting a reticular pattern of the so called cobblestone type. This pattern is not readily obliterated by pressure, as is usually the case in normal variation of mucosal pattern. These findings are associated with spasm of the duodenal bulb and a rapid passage of barium into the second portion of the duodenum. The return of the bulb mucosa to normal pattern after treatment confirms the original diagnosis, especially if correlated with improvement in symptoms (fig. 3).

Figure 3 Duodenitis. Left Contracted bulb with cobblestone mucosal pattern despite pressure over bulb. Bulb was spastic and tender at fluoroscopy. Right Normal bulb shown after medical regimen patient asymptomatic.

#### TECHNIQUES OF EXAMINATION

Techniques for the performance of gastro intestinal series are as many and varied as the preferences of examiners. It is the intention here only to emphasize certain maneuvers which may assist in the demonstration of duodenal disease, particularly in the more difficult cases.

**Fluoroscopy.** Primary emphasis should be placed upon careful fluoroscopy done by an examiner whose eyes have been well accommodated to darkness. Accommodation should be carried out for at least 20 minutes and preferably 30 minutes. It is important that fluoroscopic examination of the duodenal cap be carried out

in upright supine, and prone projections as well as in various oblique positions. Palpation should be carried out in order to empty the bulb of excessive barium and to elicit possible tenderness. Bulb filling and emptying should be carefully observed.

**Spot Films.** Spot films of the duodenal cap should always be obtained otherwise, a small percentage of duodenal ulcers will be missed. Films should, of course, be of the best technical quality possible and should be made with a pressure spot film device. Views in frontal and oblique projections should be obtained. In certain cases, particularly in examinations performed on hypersthenic individuals, demonstration of the duodenal cap which is obscured by the barium filled antrum in frontal projections can be obtained in oblique or true lateral projections. Pressure spot films of the duodenal cap should always be obtained when possible because a significant percentage of ulcers may be obscured by the barium distended bulb lumen. This is particularly true in cases which show little bulb spasm. This compression will have the effect of displacing the barium from the bulb with the exception of that which is collected in the ulcer crater. Around the crater a radiolucent halo is frequently seen in the area of adjoining mucosal edema (fig 4).

Figure 4 Central crater demonstrated by pressure spot film. Left Usual oblique view appears normal. Right Pressure spot film obtained at same examination clearly shows crater.

**Spot Films With Patient in Prone Position.** Under some circumstances however, compression spot films may not be possible when the duodenal bulb is located under the right costal margin. This again is particularly true in hypersthenic individuals. In

such cases, prone spot films may be of definite value because the pressure of the table against the patient's abdomen may be sufficient to somewhat empty the duodenal bulb. Prone spot films may also be of considerable value when the duodenal bulb is so irritable or spastic that it will not remain filled in the upright position sufficiently long to obtain good spot films. The method will also overcome the problem of air trapped in the duodenal bulb, often encountered when the patient is examined upright. The prone method may also be expected to delineate a shallow anterior wall ulcer otherwise not demonstrable (fig. 5).

*Figure 5 Apical crater demonstrated by spot film with patient in prone position. Left: Usual oblique view appears normal. Right: Oblique spot film patient in prone position, right side dependent, clearly shows apical crater.*

**Air Contrast Spot Films.** In hypersthenic individuals in whom palpation of the duodenal bulb is not possible, air contrast examination of the duodenal cap is frequently of value, particularly when a crater in the posterior wall is present. With the patient in the supine position and the right side slightly elevated, the gas bubble normally present in the stomach is displaced into the antrum. Within a short time some gas will pass through the pylorus into the duodenal cap, allowing visualization of the crater through the air-filled bulb as described by Hampton<sup>13</sup> and emphasized by Meyer<sup>14</sup> (fig. 6). If the gas bubble in the stomach is small or absent, a small quantity of carbonated material or Seidlitz powders can be given, as suggested by Hinkel and Moller.<sup>15</sup> In some instances of very shallow ulcers of the posterior wall this method is the only one by which the crater can be shown.

**Demonstration of Bulb Through Air Filled Antrum.** When some patients are turned obliquely in either the upright or prone position, the duodenal bulb cannot be seen against the barium-filled body of

the stomach. Once again this is particularly true of hyper theic individuals in whom the bulb cannot be seen in frontal projection either. In these individuals spot films of the duodenal bulb through

Figure 6 Crater demonstrated by air contrast bulb technique. Left Crater is seen in profile. Right Another niche is seen en face.

the air filled antrum may be the only method allowing visualization of the cap (fig 7). This may be easily carried out by using a small quantity of barium and carbonated beverage or Seidlitz powder.

Figure 7 Crater demonstrated through air contrast antrum. Left Barium-filled antrum obscures bulb. Note retained food particles. Bulb could not be seen in oblique or lateral projections whether patient was upright, prone or supine. Right Crater shown through air filled antrum on repeat study done with Seidlitz powders. Crater confirmed at operation.

**Other Views** In rare instances certain other views may be of value in demonstrating the bulb that is difficult to visualize in the usual way. Among these are a lateral film made with the patient prone. This drops the stomach anteriorly away from the posterior

fixed duodenum. A decubitus film with the patient lying on the left side will allow displacement of the stomach to the left of the relatively fixed duodenum and may allow a clear demonstration of the cap.

### HEALING OF DUODENAL ULCER

The problem of recognizing healing of a duodenal ulcer by roentgenography has been stated to be more difficult than the actual demonstration of the ulcer itself. Certainly a duodenal ulcer may be diagnosed as healed if the duodenal cap returns to an absolutely normal appearance (fig. 8). However, the presence of some residual

Figure 8. Healing of duodenal ulcer. Left: Pressure spot film shows crater. Right: Normal bulb after seven weeks of medical treatment.

deformity, even if a crater can no longer be shown, does not permit the diagnosis of healed duodenal ulcer. Small ulcerations may go undetected because of the deformity. The absence of irritability or spasm of the duodenal cap is of considerable importance, but these findings, particularly when minimal, are frequently difficult to assess. Diagnosis of healing based on the absence of these signs should be made with caution. In the presence of a deformed duodenal bulb, the most reliable criterion is the finding of persistent unchanged deformity despite the lack of prolonged observation. This should be correlated with the absence of clinical symptoms or signs.

Rarely, an apparent crater may persist indefinitely. In actuality, this is not a crater but a cicatricial pocket, healed but with enough depth to collect barium. Again, prolonged observation without evidence of change in asymptomatic individuals distinguishes this from an active ulcer (fig. 9). At times such a pocket may be

so large that it simulates a duodenal diverticulum. Under many circumstances strong pressure may be brought to bear on the radiologist to state whether or not the ulcer is absolutely healed. Temptation to make a definite statement should be resisted until observation shows that no change in the deformity has taken place for several weeks or, preferably months.

Figure 9 Healing of duodenal ulcer. Persistence of central accumulation of barium with Forssell's mucosal corona observed without change for 10 months in an asymptomatic patient. Accumulation of barium represents a healed cicatricial pocket with puckered bulb.

## SUMMARY

The incidence of duodenal ulcer is increasing, and its accurate diagnosis in members of the Armed Forces is of extreme importance. Careless or inept examinations are less than valueless, they can do much harm by resulting in erroneous opinions. Because of the heavy reliance placed on the roentgenographic diagnosis and follow-up of patients, the primary and secondary signs of duodenal ulcer have been reviewed and certain technical maneuvers for the resolution of more difficult cases have been reported and demonstrated.

so large that it simulates a duodenal diverticulum. Under such circumstances strong pressure may be brought to bear on the radiologist to state whether or not the ulcer is absolutely healed. Temptation to make a definite statement should be resisted until observation shows that no change in the deformity has taken place for several weeks or preferably, months.

Figure 9 Healing of duodenal ulcer. Persistence of central accumulation of barium with Forssell's "mucosal corona," observed without change for 1 month in an asymptomatic patient. Accumulation of barium represents healed cicatricial pocket with "puckered bulb."

expensive, and all plastic parts are discarded after each case. Basically, it consists of a blood inlet tube, an oxygen inlet tube, a diffusion disk, a vertical oxygenating tube, a debubbling cham-

Figure 1 Pump oxygenator for cardiac bypass (A) Venous end of Sigmamotor pump receiving inflow from venae cavae and coronary sinus reservoir pumping blood into oxygenating tube (B) Oxygen inlet (C) Oxygenating tube (D) Debubbling chamber (E) Helix reservoir in water bath (F) Blood filter (G) Arterial end of pump (H) Reservoir and pump for return of blood from coronary sinus (I) Reservoir for measuring blood loss via suction.

ber, and a helix reservoir for additional debubbling. The debubbling chamber is thinly coated with Antifoam A. Blood is withdrawn from the patient through catheters in the superior and inferior venae cavae and returned to the patient via a catheter placed in the lumen of the aorta through the subclavian artery. A Sigmamotor pump is utilized in the circuit.

The following is a report of the first three cases of intra cardiac surgery performed with the aid of an artificial oxygenator at this hospital

### CASE REPORTS

**Case 1** A 27 month-old boy had suffered some decreased exercise tolerance accompanied by frequent upper respiratory infections, cyanosis and syncope since birth. His condition had become progressively worse prior to his final admission on 25 July 1956. On 8 February 1956 cardiac catheterization (table 1) was performed followed by angiocardiology. Catheterization revealed a left to right shunt at the atrial level, pulmonary stenosis, and a persistent left superior vena cava. Angiocardigrams suggested the presence of an intraventricular septal defect in addition to the other anomalies. Physical examination revealed a poorly developed cyanotic child.

TABLE 1 Cardiac catheterization on data for case 1

	Oxygen saturation (per cent)	Pressure (mm Hg)
Superior vena cava (left)	70	
High	87	
Low	60	
Superior vena cava (right)	71	16/6
Inferior vena cava	81	100/0
Right atrium	82	24/10
Right ventricle	81	105/68
Pulmonary artery	62	
Femoral artery		

The blood pressure was 105/68 mm Hg and the erythrocyte count was 6 000 000/ $\mu$ l. There was a loud harsh systolic murmur audible over the entire precordium, loudest in the second and third intercostal space to the left of the sternum. A systolic thrill was also palpable in this region. Roentgenograms revealed right ventricular and left atrial enlargement with a decrease in the pulmonary vascular markings. On 27 July an operation was performed via a transverse bilateral anterior thoracic incision. It was noted that the left superior vena cava entered the left atrium. This vessel was then ligated. Total cardiac bypass was accomplished with perfusion by means of the pump oxygenator. A right ventriculotomy was performed and a 1 by 1½ cm intraventricular septal defect was repaired with the aid of a patch of Ivalon (brand of polyvinyl) sponge. The defect was located high in the right ventricle. A pulmonary valvotomy was performed relieving the pulmonic stenosis. Through an atrial incision a 2 by 2½ cm atrial septal defect was repaired by direct suture. Total

cardiac bypass lasted 31 minutes Postoperatively, the patient did moderately well, however complete heart block which had ensued following closure of the atrial septal defect persisted Thirty six hours postoperatively, respiratory difficulty and cyanosis appeared A tracheostomy was performed with some temporary improvement but 12 hours later cyanosis and circulatory failure recurred, followed by death

**Comments** Autopsy revealed complete repair of the defects Death can be attributed to cardiac failure subsequent to repair of multiple defects and persistence of complete heart block.

**Case 2** A six year-old girl had a heart murmur since infancy, retardation of growth, frequent respiratory infections and exercise intolerance Cyanosis of the lips had been noted on occasion Physical examination revealed a loud systolic murmur over the precordium, most prominent in the fourth intercostal space to the left of the sternum accompanied by a marked thrill The blood pressure was 100/60 mm Hg and the second pulmonic sound was somewhat prominent Roentgenograms revealed an enlarged right ventricle with evidence of increased pulmonary blood flow Cardiac catheterization (table 2) on 22 October 1955 revealed a left to right shunt at the ventricular level and a 40-mm pressure gradient across the pulmonic valve Systemic arterial

TABLE 2 Cardiac catheterization data for case 2

	Oxygen saturation (per cent)	Pressure (mm Hg)
Superior vena cava	58	
Inferior vena cava	68	
Right atrium	55	20/5
Right ventricle	77	100/0
Pulmonary artery	77	60/18
Left pulmonary artery		44/16
Femoral artery	86	100/60

oxygen saturation was 86 per cent These findings were interpreted as consistent with the tetralogy of Fallot accompanied by a bidirectional shunt On 14 August 1956 a right ventriculotomy was performed and a high 1.5 by 1 cm ventricular septal defect with firm fibrous edges was closed with a series of interrupted silk sutures Pulmonary infundibular stenosis was present and relieved by excision of the obstructing tissue Postoperatively the patient did well until the evening of surgery at which time repeat thoracotomy was necessitated by a bleeding from a small coronary artery Subsequently the patient had an uneventful postoperative course and was discharged on the 21st postoperative day At the time of discharge there was no thrill and only

a Grade 1 systolic murmur was audible over the pulmonic area. The patient is doing well five months after operation

Comments "Overriding of the aorta," a classical concomitant of the tetralogy of Fallot is more a functional than anatomic factor. Repair of the ventricular septal defect in these cases presents little more difficulty than encountered in repair of ventricular septal defect unaccompanied by pulmonary obstruction

Case 3. A two and one-half year old Hawaiian boy was admitted to this hospital on 29 August 1956. He had had six previous hospitalizations for bronchopneumonia and cardiac failure. A cardiac murmur had been detected shortly after birth and he had received digitalis since the age of six months. Development had been normal weight gain was poor in the interim between hospital stays he manifested moderate exercise intolerance. Physical examination revealed a bulging precordium with a harsh systolic murmur and thrill most prominent in the fourth intercostal space to the left of the sternum. The second pulmonic sound was markedly accentuated. Roentgenograms showed tight ventricular hypertrophy and some left atrial enlargement. Electrocardiogram was characteristic of right ventricular hypertrophy. Cardiac catheterization data is shown in table 3. On 6 September using the artificial oxygenator a large 2.5 cm ventricular septal defect

TABLE 3 Cardiac catheterization data for case 3

	Oxygen saturation (per cent)	Pressure (mm Hg)
Superior vena cava	64	
Inferior vena cava	67	
Right atrium	60	94/0
Right ventricle	72	75/37
Pulmonary artery	72	121/82
Femoral artery	98	

was repaired through a ventriculotomy incision. The defect was located posteriorly and high in the septum the tricuspid annulus comprising the right margin of the defect. A pledget of polyvinyl sponge was used to buttress the closure. Cardiac bypass lasted 42 minutes. Postoperatively the patient had an uneventful course. A soft systolic pulmonic murmur persists. The thrill has disappeared. A roentgenogram of the chest revealed decreased engorgement of the pulmonary vessels.

Comments To date (five months postoperative) this child has done well. Both patients (cases 2 and 3) have had no respiratory infections postoperatively. The mothers have been amazed by the marked increase in the activity of these two children.

## SUMMARY

An artificial bubble oxygenator has been used in the repair of a congenital cardiac defect in three children. Successful repair was accomplished in one child with a ventricular septal defect, and in a second with the tetralogy of Fallot. A third patient with the tetralogy of Fallot and a left superior vena cava draining into the left atrium, succumbed from the combined effects of complete heart block and congestive heart failure.

## FACT AND FANCY

It is not easy for the student or physician to move through a busy career and maintain a lively curiosity. Too often we encounter satisfaction and even complacency in the state ment. We must not go beyond the facts. 'I belong to a school which holds that we must encourage our pupils to let fancy roam where it will. The danger line between fact and fancy will never be obscured when fancy is habitually encouraged to formulate tests whereby its truth may be examined."

# MITRAL COMMISSUROTOMY AT AN ARMY HOSPITAL

DAVID E THOMAS Lieutenant Colonel MC USA

**M**ANY people have contributed to the development of mitral commissurotomy as a standard operation for mitral stenosis. To mention a few, Souttar<sup>1</sup> in 1920 used a technic similar to that employed today and had a successful result in one case. His colleagues were so unimpressed or alarmed that no more cases were so unimpressed of this century, the 80 per cent mortality in the third decade justified a gloomy outlook for surgical treatment.

Bailey<sup>2</sup> inaugurated the modern era by performing an unsuccessful finger fracture of the mitral valve in 1916. He as well as Harken and associates<sup>3</sup> performed successful valvulotomies with instrumental aid in 1948. Following these pioneer efforts progress was rapid and at the present time there are many 3 to 5 year follow up reports in the literature.

Most articles report an operative mortality varying from 0 per cent<sup>4</sup> to 20 per cent<sup>5</sup> in Class IV cases. Huzman and associates<sup>6</sup> reported an over all mortality of 9 per cent in 67 cases with the rate varying from 0 per cent in Class II to 30 per cent in Class IV. Mortality was high if associated aortic valve lesions were present. Eighty four per cent of the patients had an excellent to good result on 1 to 2 year follow up. From 1 000 cases followed up to 7 years Bailey and Bolton<sup>7</sup> found that (1) nearly 90 per cent of the survivors were improved, (2) the early mortality rate was 8 per cent, (3) late deaths accounted for 5.6 per cent and (4) that mild postoperative mitral insufficiency was of no significance but that marked insufficiency was very serious. They also observed that recurrences do happen.

Swann and associates<sup>8</sup> believed that the degree of calcification of the valve determined the postoperative result, while Bafer Brock, and Campbell<sup>9</sup> showed that irrespective of calcification the result correlated with what the surgeon believed he accomplished—the larger the postoperative orifice without regurgitation the better the result. These authors also showed

From Fitzsim as Army II Pital Denver Colo. Lt Col. Thomas is now assigned to Valley Forge Army Hospital Phoenixville Pa.

that (1) the percentage of patients in the excellent category declined slightly year by year; (2) restenosis can occur with further rheumatic activity, and (3) that pulmonary hypertension, when checked by cardiac catheterization a year or two after commissurotomy, reverts to normal in cases having an excellent result

Glover, O'Neill, and Janton<sup>9</sup> showed that only 8 per cent of 50 patients on 5 year follow-up had no murmurs, 19.5 per cent had postoperative evidence of rheumatic activity, and 24 per cent had smaller cardiac silhouettes

### PRESENT STUDY

This analysis includes 33 consecutive cases in which operation was performed from October 1953 to January 1955. In one of the cases, reoperation was necessary. The patients were placed in four categories closely corresponding to those used by the American Heart Association (table 1)

TABLE 1 *Clinical classification of patients with mitral stenosis*

Class	Number of patients
I Physical signs of mitral stenosis are present, but the patient is asymptomatic	4
II The patient is symptomatic, but there are only minor limitations of activity and the process is not showing progression	13
III Symptoms are progressive there is moderate to marked limitation of activity the patient may exhibit auricular fibrillation hemoptysis, acute pulmonary edema and has only a limited response to cardiac drugs and bed rest	14
IV The patient is bedridden with chronic heart failure	2
Total	33

Only 1 of our patients was on active duty, 1 was retired, 1 was a Red Cross worker, and 30 were civilian dependents. This is readily explained since rheumatic disease is a cause of rejection for military service.

The distribution according to age noted in table 2 corresponds with that generally found. This indicates that mitral stenosis most often causes the patient to seek aid between 20 and 40 years of age. Three of the six deaths occurred in patients of ages between 47 and 59 years.

TABLE 2 Age distribution of patients

Age (years)	Number of patients
Less than 20	2
20 to 30	12
30 to 40	12
40 to 50	6
50 plus	1
Total	33

As table 3 indicates mitral stenosis without insufficiency was the lesion most commonly found. Insufficiency of varying degree was found in a significant number of cases this sometimes having been diagnosed prior to operation. Commissurotomy in the presence of slight insufficiency was found to be indicated since the procedure seldom increased and occasionally decreased the amount of regurgitation. However, as will be discussed the postcommissurotomy regurgitation syndrome is a real entity and one to be feared.

TABLE 3 Lesions encountered at operation

Lesion	Number
Mitral stenosis	25
Mitral stenosis with insufficiency	7
Multivalvular	2
Other (pneumonia)	1

The early mortality rate in this series was 12 per cent total 18 per cent. Operative complications were far from unusual and included 3 auricular tears, 2 ventricular fibrillations, 1 cardiac standstill, 1 ventricular tear, 1 cerebral embolus, 1 marked regurgitation after commissurotomy requiring attempt at operative

correction, 1 inadequate commissurotomy due to a small auricular appendage, and the incidental finding of an early virus pneumonia with serofibrinous pleurisy. Postoperative complications included 4 cases of persistent auricular fibrillation, 2 cases each of thrombophlebitis, hydrothorax, and pericardial effusion, 1 atelectasis, and 1 bacterial endocarditis and septicemia caused by *Micrococcus pyogenes var albus*.

Poor results (table 4) included one unsuccessful operation due to a small auricular appendage. This patient was reoperated on under hypothermia with a bilateral approach and his status changed from Class III to Class I. The other poor results were due to postcommissurotomy mitral regurgitation in three patients.

TABLE 4 Operative results

Commissurotomy method	Total number of operations	Results			
		Improved	Unimproved or worsened	Died	
				Early	late
Finger fracture	33	23	4	1	2
Use of valvulotome	1	1			
Total	34	24	4	4	2

Two of these operations were on the same patient.

Operative deaths included a Class IV, 59 year old man with trivalvular disease and extensive arteriosclerosis who was accepted for commissurotomy knowing he was a very poor risk. A 47 year old, female, Class II patient, considered to be an excellent operative risk, developed ventricular fibrillation, during surgical intervention, that converted only after a prolonged period. She never regained consciousness and died of bronchopneumonia during the early postoperative period. Cerebral embolism prior to opening the auricle caused death in a 47 year-old, Class II patient who had fibrillation. It is interesting to note that 3 of the 4 deaths occurred in our 7 patients over 10 years of age.

The fourth death occurred in a 29 year old, Class II patient who at thoracotomy was found to have an early virus pneumonia. The lungs were heavy and serofibrinous pleurisy was present. The patient developed marked regurgitation after commissurotomy. This was repaired by placing a transventricular suture in the posterior commissure. In addition, temporary cardiac standstill occurred when the pericardium was closed. This unfortunate patient died of bronchopneumonia on the fourth postoperative day.

Late deaths included that of a 35 year old, Class IV patient with a diagnosis of mitral stenosis and insufficiency and aortic insufficiency. She developed or had a reactivated bacterial endocarditis and septicemia caused by *M pyogenes* var *albus* and died two and one-half months after surgical intervention.

The other late death occurred in a 24 year old Class I patient who was operated on because pulmonary hypertension had been demonstrated. The preoperative diagnosis was mitral stenosis and insufficiency. The operation was uneventful. A stenotic orifice was adequately fractured without creating significant insufficiency. During her convalescence auscultation revealed a marked decrease in the diastolic murmur. She gradually developed cardiac decompensation and died elsewhere 17 months after commissurotomy. Autopsy revealed a severe mitral stenosis. One can only conclude that the leaflets reapposed.

Examination three to six months after surgical intervention generally reveals the usual physical signs of mitral stenosis. Two patients revealed normal physical findings and these patients, one over 40 years of age, have had excellent results. As has been mentioned before, the murmur of mitral insufficiency is frequently heard postoperatively. This is associated with a poor result only if the degree of insufficiency is severe.

### CONCLUSIONS

The surgical relief of mitral stenosis is not without hazard, inasmuch as it carries a significant operative mortality and may actually result in symptomatic worsening of the patient. However, in the properly selected patient, improvement after surgical intervention is the usual outcome and results may be dramatic. This study suggests that patients with great care. Operation on Class IV patients and those with multivalvular disease has a greatly increased risk. Class I patients should not be operated on but should be followed and surgical intervention recommended at such time as progression becomes apparent.

While mitral commissurotomy is one of the simpler cardiac operations, it is not one to be recommended casually. It carries a significant operative and late operative mortality and may be followed by a progression of symptoms. The value derived justifies the risks involved in the properly selected case.

#### BLOOD GROUPS AND GASTRIC CANCER

"In 119 cases of carcinoma of the stomach the excess of blood group A over blood group O was due to an association between group A and carcinoma of the pyloric end of the stomach

"There was no excess of group A in carcinoma arising in the body of the stomach and hence this material provides no support for the hypothesis that group A is associated with atrophy of the acid producing mucosa and achlorhydria

"The antral mucosa of persons with blood of group A is apparently more liable to inflammation and carcinoma than that of group O persons "

# EVALUATION OF PANCREATIC EXOCRINE FUNCTION AND INTESTINAL ABSORPTION WITH RADIOACTIVE FAT

## Preliminary Report

RICHARD P. SPENCER *Lieutenant MC USNR*  
CHARLES R. HENKELMANN *Lieutenant MC USNR*  
E. PICHARD KING *Captain, MC USN*

**L**IPASE, a pancreatic enzyme converts fats to fatty acids and glycerin, which are then absorbed from the alimentary canal. When the enzyme is present in sufficient quantity and intestinal absorption is normal, the healthy adult will take up almost 100 per cent of orally administered radioactive fat (olein [triolein] labeled with iodine 131). Failure to absorb the entire dose results in the appearance of abnormal quantities of iodine 131 ( $I^{131}$ ) tagged fat in the stool. Such a finding indicates that either (1) the production or delivery of pancreatic lipase to the gut is deficient or (2) the absorptive apparatus is at fault. The technic used in this study is less complicated than previous procedures<sup>1</sup> for the evaluation of pancreatic and intestinal function with radioactive fat.

## METHOD

Olein  $I^{131}$  is added to a small quantity of a carrier (composed of 200 ml of peanut oil, 200 ml of water, and 15 ml of Tween 80) and is stored for future use. When a dose is to be made, an aliquot containing 25 microcuries of radioiodine is drawn off and diluted with carrier so that the final volume taken by the patient is 1 ml per kilogram of body weight. Another sample is made up in identical fashion, to be used as the standard. Traces of radioactive fat cling to the cup from which the patient drinks the olein  $I^{131}$ . Hence this cup is saved so that its radioactivity can be determined and subtracted from the standard in calculating the dose ingested as discussed below.

The patient drinks a suspension of 10 drops of Lugol's solution and a suitable indicator (such as carmine dye or charcoal) in

---

From Radiology Laboratory, U. S. Naval Hospital Bethesda, Md.

60 ml of water. The Lugol's solution presents the body with a large dose of iodine and prevents significant uptake of radioiodine by the thyroid gland. The indicator is used to mark the complete passage of the material through the digestive tract, and obviates the use of roentgenograms with barium swallow. Immediately after this medication, the patient drinks the olein  $I^{131}$  and carrier mixture.

All stools are saved after the fatty mixture is ingested until traces of the charcoal or carmine marker no longer appear. It would be less accurate to specify an arbitrary number of days required for stool collection. Probably as a result of patients' inactivity in the hospital several days may pass before all the radioactive material has been excreted by some patients. Specimens are collected in 1 quart, leak proof containers and are kept cool or refrigerated to reduce odor and bacterial activity. The standard is also refrigerated to prevent deterioration of the fat. It is of the utmost importance that no urine contaminates the stool, this caution must be repeatedly emphasized to the patients, and also the nursing staff if the procedure is performed in the hospital.

To maintain approximately constant volume, the standard and the cup from which olein  $I^{131}$  was drunk are placed in separate, 1-quart containers, water is added to the top, and the containers are shaken thoroughly after the covers are replaced. Water is also added to the 1 quart container holding the stool sample, and it is also shaken. A scintillation counter (sodium iodide, thallium activated) is used for the radioassays. The container is placed 20 cm from the detection probe, at this distance, the solid angle viewed by the probe includes the entire container. Counts of background, standard, cup, and stool are taken for 3 minutes. The standard registers approximately 25,000 counts during the 3 minute interval, which is well above the background count.

The percent of the administered dose of olein  $I^{131}$  which appears in the stool, may be calculated as follows:

$$\frac{(\text{counts in stool} - \text{background}) \times 100}{(\text{counts in standard} - \text{background}) - (\text{counts in cup} - \text{background})}$$

or, more simply by

$$\frac{(\text{counts in stool} - \text{background}) \times 100}{(\text{counts in standard} - \text{counts in cup})}$$

The individuals undergoing this study were from the medical services of this hospital. Two groups took the test, those with gastro-intestinal disorders and patients with other diseases but without known active alimentary dysfunction.

## RESULTS

Typical results obtained are presented in table 1. The patients in this table were the first 10 individuals on whom the test was performed. Our total series at present includes nearly 30 cases. Although this total number of cases are not fully evaluated, the average excretion in this group both normal and abnormal appears to be *identical* with that of the 10 patients in this preliminary report. Fecal excretion of olein I<sup>131</sup> (or its metabolites) by the "normal" subjects averaged 1.8 per cent ( $\pm 0.8$ ) of the ingested dose ( $\pm 0.8$  is two standard deviations). Elevated excretion of olein I<sup>131</sup> was found to range from 4 per cent (in a male who had a subtotal gastrectomy) to over 50 per cent (in a patient with biliary obstruction due to metastatic carcinoma).

TABLE 1 Stool excretion of olein I<sup>131</sup> in adult patients

Sex	Age (years)	Diagnosis	Excretion in per cent of administered dose
<i>Normal Excretion</i>			
M	24	Nematode infestation	1.7
F	51	Brucellosis	2.0
M	34	Diabetes mellitus	1.3
M	63	Carcinoma of abdomen ? primary	2.3
M	25	Inactive peptic ulcer (duodenal)	1.5
<i>Elevated Excretion</i>			
M	30	Subtotal gastrectomy	4.0
F	68	Sprue in remission	5.9
M	37	Alcoholism chronic pancreatitis	10.4
M	33	Alcoholism active duodenal ulcer ? pancreatitis	10.6
M	55	Ampulla of Vater obstruction of and jaundice due to metastatic carcinoma of colon	50.1

## DISCUSSION

The technic merits further investigation because it offers a means of studying pancreatic function and intestinal absorption—two systems that are notoriously difficult to evaluate. The test is economical for the total cost of the olein-I<sup>131</sup> and carrier is less than a dollar per patient. It can be performed by any laboratory that is equipped to do 24-hour thyroid I<sup>131</sup> uptake studies. Furthermore, there is no trauma to the patient. The procedure

may be done on an outpatient basis, or can be performed while the individual is in the hospital undergoing other diagnostic tests, provided they do not interfere with digestive function or stool collection. The present technic is simplified over previous methods in three respects:

1 A readily detectable dye, such as charcoal or carmine, is used to mark the passage of the ingested material through the digestive tract. Hence, barium swallow and fluoroscopy are not necessary to indicate when the material has been passed. Use of a dye enables the procedure to be done on an outpatient basis.

2 Determination of  $I^{131}$  blood levels are not required. There is no specific indication, therefore, for hospitalizing the patient.

3 The use of one solution as the carrier facilitates handling by the physician or his technicians.

Either a deficit of pancreatic lipase or a decreased absorption of lipids will result in the appearance of fat tagged with radioiodine in the stool. If pancreatic function were normal, then the olein would be split to fatty acids and glycerin, even though absorption were at fault. Hence, a further refinement of the technic would be to fractionate the stool specimen,<sup>2</sup> to observe if the radioactivity is present as olein  $I^{131}$  or its digestion product, oleic acid  $I^{131}$ .

The detection of greater than normal quantities of radioiodine fat in the stool of a postgastrectomy patient has also been noted by Sanders and his co-workers.<sup>1</sup> This may partially account for the nutritional disturbance seen in those who have had their stomach removed, and suggests the possibility that the gastric mucosa produces a substance necessary for the absorption of fat by the intestines.

### SUMMARY

A simplified test using fat tagged with radioiodine in the evaluation of a deficiency of pancreatic exocrine function, or errors in alimentary absorption, is described. The test is easily performed and inexpensive.

Patients with disorders that decrease the amount of pancreatic enzymes reaching the gut (chronic pancreatitis, obstruction of the Ampulla of Vater), and those with decreased intestinal absorption of fats (such as sprue), excrete more of an ingested dose of olein (triolein)  $I^{131}$  in their stool than do adults without active gastro intestinal disease.

Increased stool olein  $I^{131}$  excretion was also observed in a postgastrectomy patient, and a possible role for fat absorption by the gut is discussed.

## RESULTS

Typical results obtained are presented in table 1. The patients in this table were the first 10 individuals on whom the test was performed. Our total series at present includes nearly 30 cases. Although this total number of cases are not fully evaluated, the average excretion in this group, both normal and abnormal, appears to be identical with that of the 10 patients in this preliminary report. Fecal excretion of olein I<sup>131</sup> (or its metabolites) by the "normal" subjects averaged 1.8 per cent ( $\pm 0.8$ ) of the ingested dose ( $\pm 0.8$  is two standard deviations). Elevated excretion of olein I<sup>131</sup> was found to range from 4 per cent (in a male who had a subtotal gastrectomy) to over 50 per cent (in a patient with biliary obstruction due to metastatic carcinoma).

TABLE 1. Stool excretion of olein I<sup>131</sup> in adult patients

Sex	Age (years)	Diagnosis	Excretion in per cent of administered dose
<i>Normal Excretion</i>			
M	24	Nematode infestation	1.7
F	51	Brucellosis	2.0
M	34	Diabetes mellitus	1.3
M	63	Carcinoma of abdomen - primary	2.3
M	25	Inactive peptic ulcer (duodenal)	1.5
<i>Elevated Excretion</i>			
M	30	Subtotal gastrectomy	4.0
F	68	Sp. ulcer in remission	5.9
M	37	Alcoholism - chronic pancreatitis	10.4
M	33	Alcoholism - active duodenal ulcer ? pancreatitis	10.6
M	55	Ampulla of Vater obstruction of and jaundice due to metastatic carcinoma of colon	50.1

## DISCUSSION

The technic merits further investigation, because it offers a means of studying pancreatic function and intestinal absorption, two systems that are notoriously difficult to evaluate. The test is economical for the total cost of the olein I<sup>131</sup> and carrier is less than a dollar per patient. It can be performed by any laboratory that is equipped to do 24 hour thyroid I<sup>131</sup> uptake studies. Furthermore, there is no trauma to the patient. The procedure

may be done on an outpatient basis, or can be performed while the individual is in the hospital undergoing other diagnostic tests, provided they do not interfere with digestive function or stool collection. The present technic is simplified over previous methods in three respects:

- 1 A readily detectable dye, such as charcoal or carrier, is used to mark the passage of the ingested material through the digestive tract. Hence, barium swallow and fluoroscopy are not necessary to indicate when the material has been passed. Use of a dye enables the procedure to be done on an outpatient basis.
- 2 Determination of  $I^{131}$  blood levels are not required. The  $I^{131}$  is no specific indication, therefore, for hospitalizing the patient.
- 3 The use of one solution as the carrier facilitates handling by the physician or his technicians.

Either a deficit of pancreatic lipase or a decreased absorption of lipids will result in the appearance of fat tagged with radioiodine in the stool. If pancreatic function were normal, then the olein would be split to fatty acids and glycerin, even though absorption were at fault. Hence, a further refinement of the technic would be to fractionate the stool specimen to observe if the radioactivity is present as olein  $I^{131}$  or its digestion product, oleic acid  $I^{131}$ .

The detection of greater than normal quantities of radioiodine fat in the stool of a postgastrectomy patient has also been noted by Sanders and his co-workers.<sup>1</sup> This may partially account for the nutritional disturbance seen in those who have had their stomach removed, and suggests the possibility that the gastric mucus produces a substance necessary for the absorption of fat by the intestines.

### SUMMARY

A simplified test using fat tagged with radioiodine in the evaluation of a deficiency of pancreatic exocrine function, or errors in alimentary absorption, is described. The test is easily performed and inexpensive.

Patients with disorders that decrease the amount of pancreatic enzymes reaching the gut (chronic pancreatitis, obstruction of the Ampulla of Vater), and those with decreased intestinal absorption of fats (such as sprue), excrete more of an ingested dose of olein (triolein)  $I^{131}$  in their stool than do adults without active gastro intestinal disease.

Increased stool olein  $I^{131}$  excretion was also observed in a postgastrectomy patient, and a possible role of the stomach in fat absorption by the gut is discussed.

## PLASMA AMYLASE IN RENAL INSUFFICIENCY

Plasma amylase concentration may be markedly elevated in some cases of acute renal insufficiency without implying an associated acute pancreatitis. Although trauma, opiates and possibly chemical derangements may enhance amylase concentration by increased production, the diminished urinary excretion appears to be the major cause of the protracted and exaggerated levels. When chemical and clinical uremia was modified by artificial kidney dialysis the plasma amylase was not consistently affected and fluctuated at high levels. The urine plasma amylase was found to vary greatly and was not therefore of diagnostic import.

# PRACTICAL ALLERGY PROGRAM FOR SMALL MILITARY INSTALLATIONS

MERLE S. SCHERR *Captain MC USA*

**F**ACILITIES for the care of allergic patients in military installations usually have been limited to the larger hospitals, although some small hospitals have had basic facilities for medical officers who were interested in the specialty. The need for a practical allergy program for the smaller hospitals and clinics has long been recognized. This article outlines a basic program for military physicians to use in treating allergic patients in units where a qualified allergist is not available. A complete allergy program has been described in a technical bulletin.<sup>1</sup>

The majority of patients treated without referral to a large hospital will be those with seasonal and perennial allergic rhinitis, mild bronchial asthma, and related disorders. Because these patients do not need to be hospitalized, a practical plan for treating them in the small clinic or hospital will save time, transportation, and money, and will permit them to begin and continue treatment under the care of the same medical officer.

## CONTROL OF DUST AND DIET

This article deals primarily with the requirements for basic skin testing and treatment, and if proper dust precautions and dietary studies are used, a large amount of testing of the average patient will be unnecessary. The physician should instruct the patient in procedures designed to free his environment of the common inhalants and allergens such as feathers, house dust, animal danders, and fly spray. Suggested directions for the preparation and maintenance of a dust free room, which should be followed to the fullest extent that conditions permit, are as follows:

For best results the home and environment of dust sensitive persons must be maintained as free from dust as possible. In at least one room all sources of dust should be eliminated. The bedroom is usually the most suitable for this purpose.

From Fitzsimons Army Hospital Denver, Colo. Dr. Scherr is now at 603 Atlas Bldg., Charleston, W. Va.

All rugs curtains and drapes should be removed. The room should contain only one bed preferably an iron one. If a second bed is necessary it also must be prepared as described. Wash the bed springs and slats thoroughly. Cover the pillows mattress and springs (if box type used) with allergen proof encasings. The encasings must be sealed or sewed on to ensure airtightness. The bed should be made up frequently with fresh plain linen. No mattress pad should be used. Coverings should be plain and washable. Stuffed comforts or quilts are not permissible.

The walls floors picture molding baseboards and furniture should be washed and the woodwork preferably waxed. Furniture including chairs should be wooden and easily washable. Upholstered or cloth covered chairs are not permissible.

All bookcases pictures or wall plaques should be removed and all cracks and holes sealed. Furnace pipes leading into the room should be sealed. If hot air heat must be used outlets should be covered with cheesecloth or preferably the system air conditioned and filtered. Radiators should be scrubbed.

The room should be cleaned daily and thoroughly cleaned once a week. Closets should be cleaned the same as the room and clothing kept elsewhere. Avoid moth proofing and deodorants as the ingredients are possible allergens.

If the patient is a child do not keep toys in the room except for washable toys that will not accumulate dust. No stuffed toys are allowed.

Dressing and undressing should be done outside this room which should be used for resting and sleeping only. Avoid irritating odors such as gas paint and smoke. Do not allow pets in the house without specific permission.

The above instructions should apply to the entire house of a dust sensitive patient but practicability must be considered. However the one room should be properly prepared and maintained and the rest of the house kept as free from dust as possible. Where occupational dust conditions cannot be controlled and a change of occupation is not feasible a dust respirator should be used.

The physician should also be familiar with dietetic procedures, because proper elimination diets and food diary studies such as are described in the *Standard Army Diet Manual* will be of great diagnostic aid and usually will make it unnecessary for the patient to be subjected to skin tests for food allergens. If a complete survey is needed it should be performed at the nearest general hospital having a qualified allergist and allergy clinic.

## EQUIPMENT AND SUPPLIES

Basic equipment items such as 1 ml tuberculin syringes, one half inch No. 27 hypodermic needles, alcohol sponges, and tourniquets are available at all military medical installations. The only preparations necessary in addition to 70 per cent alcohol, diluting fluid, and 1:1,000 aqueous, injectable epinephrine will be the actual allergenic extracts. The same extracts used for treatment will be employed in weak dilutions for intradermal testing.

The basic allergens, adequate for handling most patients in the average small clinic or hospital, are house dust, feathers, mold mix (*Alternaria* and *Cladosporium*), tree pollen mix, grass pollen mix, and weed pollen mix. The tree, grass, and weed pollen mixes should contain the particular pollens found in the immediate area. A summary of important pollens by geographic regions is shown in table 1, and the physician wishing to learn in detail what pollens are present in his area may do so by consulting the standard textbooks of allergy,<sup>2,3</sup> or by writing to the Secretary, Pollen and Mold Committee, American Academy of Allergy, 208 East Wisconsin Ave., Milwaukee 2, Wis., for the complete pollen survey of the area.

Ideally, individual pollens rather than a mix should be used in testing and treatment, but it is more practicable to use mixes of the types described. Actually, in the case of grasses, most allergists believe that timothy pollen in itself contains sufficient common antigen for testing and treatment of patients sensitive to other grasses, so that timothy pollen extract can, if desired, be used in place of a grass pollen mix.

Most of the allergenic extracts that will be needed are listed in the standard medical supply catalogue. The medical officer may wish to order certain additional nonstandard items such as mixes of tree, grass, or weed pollens, or if he prefers he can make his own mixtures in the manner described in standard textbooks of allergy, using 1 ml each of various related antigens.

The extracts may be furnished in any of the commonly used strengths shown in table 2, i. e., as milligrams of total nitrogen, protein nitrogen units (PNU), or dilution of weight by volume, and proper labeling and identification is mandatory. Extracts should be refrigerated constantly but never frozen. Their refrigerator shelf life usually is about one year from date of manufacture.

## METHODS OF TESTING

Both scratch testing and intradermal testing are widely used. Where a complete survey involving a large number of tests is

# POTENTIAL INTELLIGENCE TESTING

## A Case Study

ALVIN R MAHRER *First Lieutenant MSC USAR*

FROM both a clinical and a theoretical point of view, it is useful to distinguish between a measured intelligence score (I Q) and some "potential" score that a patient is presumed capable of obtaining. A recent article<sup>1</sup> proposed general principles which related a learning theory description of potential intelligence to certain specific problems in clinical psychology (*viz* dimensions of intelligence the growth of intelligence the meaning and measurement of mental deficiency the evaluation of the extent and nature of psychological interference and psychotherapy). Clinical hypotheses may be derived from these principles.

This article illustrates how the obtaining of an index of potential intelligence level makes it possible to develop clinical hypotheses regarding an individual case. The resulting hypotheses are clinical inferences about the patient rather than precisely stated experimentally verifiable hypotheses. As a preface to the case report a brief summary is given of a learning theory approach to potential intelligence and some methods of measurement.

### LEARNING THEORY APPROACH TO POTENTIAL INTELLIGENCE

It is presumed that based on an individual's previous experiences a number of answers to any single intelligence test question are possible. Each possible answer is termed a *behavior* within the framework of Rotter's<sup>2</sup> social learning theory each possible answer (behavior) may be described in terms of *behavior potential*. This is defined as "the potentiality of any behavior's occurring in any given situation or situations as calculated in relation to any single reinforcement or set of reinforcements."

In any given testing situation there is presumed to be a set of behaviors (possible answers) for each question and the be-

behaviors in any single set vary in behavior potential from high (with the greatest relative potentiality for being verbalized) to low (with low potentiality for being verbalized). Each set of behaviors has one behavior (answer) with the highest potential. Taken together, these behaviors may be said to be at the first *level of behavior*. The behaviors with the next highest behavior potential in each set are said to be at the second level of behavior, and so on for succeeding levels of behavior. A "lower" level of behavior is lower in availability, accessibility, and potentiality for being verbalized.

It should be noted that the term levels of behavior refers to a continuum of decreasing behavior potential. The differences between levels of behavior may be slight or great. The lower the level of behavior, the lower is the potential of behaviors at that level relative to those of other levels.

The standard method of administering and scoring elicits a single answer to a single question, in other words, it bases the I Q score on the first level of behavior. Although the Wechsler Bellevue test provides for alternative "equally good" responses and responses of varying quality, the examinee is asked to give one response to each question. The I Q score calculated in this manner is termed the *standard intelligence* score and is obtained by following Wechsler's manual for Wechsler Bellevue, Forms I and II.<sup>1</sup> In contrast, scoring may be based upon the *set* of behaviors to each question or, in other words, upon all levels of behavior (all possible answers). This is termed the *potential intelligence* score.

#### SOME METHODS OF MEASURING POTENTIAL INTELLIGENCE

A method of measuring potential intelligence has been derived from the learning approach.<sup>2</sup> This method answers the general question, "What I Q score is the patient capable of attaining?" Two other methods were used with the present patient. Wechsler's deterioration index<sup>3</sup> asks a more pointed question, "What was the patient's I Q score before deterioration, impairment, or decline?" Jastak<sup>4</sup> proposed a method of estimating "altitude" intelligence, which is presumed to be related to native endowment. Whiteman<sup>5</sup> further refined this method for clinical use. These three methods were used in the case reported.

The potential intelligence method elicits a set of behaviors (answers) for each item in the following Wechsler Bellevue verbal subtests: information, comprehension, arithmetic, similarities, and vocabulary. Scoring is based on the most correct answer among the set of answers to each question. The technique of po-

tential intelligence testing is also applicable to nonverbal behavior. However, the specific performance subtests of the Wechsler Bellevue were excluded because of the large role played by speed of response and the grasping of an over all principle.

Following the standard administration (based upon level of behavior 1), the patient is encouraged to give additional answers to each incorrectly answered question. After the patient gives a set of additional answers to the missed item, the examiner proceeds to the next missed item and so on through the test. If a more correct answer is included among these additional answers, potential intelligence scoring is based upon that more correct answer rather than the first incorrect answer.

Wechsler's deterioration index is based upon a comparison of the sum of Wechsler Bellevue subtest scores which hold and those which "don't hold" with deterioration, impairment or decline. According to Whitman's refinement of Jastak's method for measuring intellectual altitude, the equivalent of 10 subtests is obtained by multiplying the highest subtest by 5, the second highest by 3, and the third highest by 2. The I Q score thus calculated is a measure of intellectual altitude.

### CASE REPORT

A 21 year old unmarried white serviceman was referred to the psychology service because of amnesia, perplexity, auditory hallucinations, ideas of reference, mild delusions of persecution, bizarre activity, confusion, and illogical thinking. The final diagnosis was schizophrenic reaction.

On the standard Wechsler Bellevue Intelligence Test, the patient's full scale I Q was 47, the performance scale I Q was 43, and the verbal scale I Q was 59. Weighted scores for five verbal subtests are given in the top row (level of behavior 1) of table 1.

The levels of behavior 2 through 6 refer to the five additional answers given to questions incorrectly answered under the standard administration. With these potential intelligence data, the following clinical hypotheses may be drawn:

### DISCUSSION

#### Probable Intelligence Level Before the Onset of Symptoms

It is useful to estimate whether the present standard verbal scale I Q score of 59 represents the patient's probable level of functioning before the onset of symptoms, or in other words, if he functioned in the mentally deficient range before the onset of symptoms. One clue to this presumptom level is the potential I Q. If this is also in the mentally deficient range, the hypothesis

is that the presymptom level was also in the deficient range. Another clue is the potential I Q score at the second or third levels of behavior. The hypothesis here is that if these potential I Q scores are so "available," they probably represent a fair estimate as to the presymptom intelligence level.

TABLE 1 *Standard and potential weighted scores on five Wechsler Bellevue verbal subtests*

Level of behavior	Information	Comprehension	Arithmetic	Similarities	Vocabulary	Verbal I Q
1	4	2	3	3	2	59
2	5	4	6	11	5	80
3	8	7	9	11	7	94
4	9	7	9	13	7	97
5	10	8	9	13	8	101
6	10	9	9	13	9	104

In this case, the potential I Q at level of behavior 6 was 104. Potential I Q's at levels of behavior 2 and 3 were 80 and 94 respectively. The hypothesis then is that this patient's I Q of 59 is probably not representative of his presymptom level of functioning, and that his presymptom level was probably in the dull normal to average range.

### The Nature of Potential Intelligence

An important step in intelligence test analysis is the investigation of the profile of high and low scores. One general principle, stated as an hypothesis, is that the "kind" of intelligence varies with different levels of behavior. Applied to a single protocol, the hypothesis is that there is no necessary relationship between the relative scores of the subtests at different levels of behavior, the "high's" of one level may be the "low's" at another. The profile of skills and abilities at one level may be quite different from that at another level, an analysis of subtests at level of behavior 1 gives little information about the skills and abilities at lower levels.

Under standard intelligence testing (level of behavior 1), only 2 points separate the "high" (information) from the "lows" (comprehension, vocabulary). Under potential intelligence testing, a new "high" subtest emerges (similarities), and the "lows" change moderately (comprehension, arithmetic, and vocabulary), with 4 points now separating the "highs" and the "lows." The clinical hypotheses are that (1) the profile of subtest scores at

lower levels of behavior differs moderately from the profile at level of behavior 1 (2) there is greater variability of subtest scores and presumably skills and abilities, at lower levels of behavior, and (3) whatever skills, abilities, and personality structure are tapped by the similarities subtest appear to be "available" and potentially high, but unexpressed at the present time

### The Mentally Deficient Classification

Two kinds of mentally deficient classifications were supported<sup>1</sup> One classification was reserved for those who are functioning at a defined low level and whose potential intelligence score also falls within the deficient class The other classification is for those whose standard I Q is below the deficiency point but whose potential intelligence rises above that point The criterion for placing an individual in either classification is the potential intelligence score

The potential intelligence score of the patient discussed rose above the mentally deficient range at level of behavior 2 (I Q 80) and scores at lower levels of behavior increased appreciably beyond the I Q of 80 Therefore, the clinical hypothesis is that although this patient is presently functioning in a mentally deficient range he is not a "true" defective in that a higher level of intellectual functioning is "available" and he probably did not function in the mentally deficient range in the past

### The Prediction of Behavior

An important use of intelligence tests is to help in the prediction of a patient's response to a variety of situations In the experimental laboratory these situations may include both simple and complex learning tasks In the clinical setting these situations may include long or short term psychotherapy, the learning of language skills social skills the development of mechanical skills retraining re education and many other situations where the intelligence level presumably plays some part The general hypothesis here is that other factors being equal with patients of similar standard I Q the response to such learning situations will correspond to the potential intelligence scores

This patient's potential intelligence score at levels of behavior 2 (I Q 80) and 6 (I Q 104) suggest that there are available responses at the dull normal or possibly normal level In comparison with patients of identical standard I Q (59) but lower potential I Q this patient would probably respond "better" to learning situations

### Potential Intelligence Native Endowment and Impairment

If a deterioration index is calculated from the data of table 1, the prorated "hold" sum is 53, and the "don't hold" sum is 6. This yields a questionable deterioration loss of -10 per cent, suggesting that no deterioration loss has occurred. The deterioration index may actually be a spurious measure with these data because it was calculated on the basis of only 5 of the 10 subtests suggested by Wechsler.

Jastak's intellectual altitude may be calculated using White man's weighting system. If this weighting system is applied to five verbal subtests, presumably the three highest scores are multiplied by  $2\frac{1}{2}$ ,  $1\frac{1}{2}$ , and 1, respectively. This yields a "native endowment" or "intellectual altitude" verbal I Q of 63. However, as with the deterioration index, these results may be spurious inasmuch as they are based on 5 subtests rather than 10, and because a questionable weighting system was used.

Nevertheless, these three measures offer apparently conflicting clinical hypotheses. Potential intelligence testing suggests that the patient is functioning from 21 to 45 I Q points below either a previous level or some theoretically potential level. In contrast, the deterioration index suggests no deterioration loss, and Jastak's method implies that the I Q score of 59 stands in relation to an "intellectual altitude" or "native endowment" I Q of 63. Such contradictory clinical hypotheses would seem to call for research to explain the differences. This case seems to demonstrate the impropriety of using the three measures interchangeably. Additional indexes of the potential intelligence level might include educational level, school grades, previous intelligence tests, and similar criteria.

### Evaluation of the Extent of Interference

One hypothesis is that the amount of interference is proportional to the amount of increase of potential over standard I Q. In the case reported, the difference of 45 I Q points must be interpreted in relation to norms. A study of 60 neuropsychiatric patients at this hospital resulted in a mean difference of potential I Q over standard I Q, of 16 I Q points, with a standard deviation of 7 points. On the basis of these limited norms, it appears that relatively high interference is present in this patient.

Another hypothesis is that the lower the level of behavior at which the potential I Q reaches a maximum and begins leveling off, the greater the interference. Until systematic norms are available, interpretation must rely on more personal and nebulous clinical experience. It appears that the leveling off of potential

1 Q's occurred between levels of behavior 3 to 6 and that the largest differences occur between levels of behavior 1 and 2 or 3. This implies that a higher level of functioning (in the dull normal or low average range) is moderately accessible or available. Tentatively, this hypothesis further suggests that in a broad sense prognosis is moderately favorable.

### Evaluating the Nature of the Interference

The evaluation of the nature of the interference may be guided by the hypotheses that behaviors of higher potential (at higher levels of behavior) than the correct behavior provide information on the nature of interfering factors. The nature of these factors may vary with each level of behavior. What is commonly accepted as a "correct" answer may not be elicited because of the greater relative potential of other answers. The following clinical hypotheses attempt to assess what factors may be operating to elicit these other answers.

At the first level of behavior there were suggestions of passive aggression (e.g. spontaneous comments such as "You've got me. Why are you asking me these things? I'm no genius how should I know? I don't know. I ain't no shoe man" to comprehension item 5) of impulsivity (e.g. "Run" to comprehension item 2) and a perseverative stimulus repetition (e.g. to vocabulary items 2, 6, 10, and 11, respectively. "A donkey means a donkey. fur means fur. bacon means bacon. nail means nail" to information item 11. "Brazil is in Brazil").

The second level of behavior also reflected passive aggression and impulsiveness, but the perseverative stimulus repetition was not found nor did it appear again at lower levels of behavior. However new factors appeared. These included impotence (e.g. to information items 10, 12, and 13 and to similarities items 6 and 7. "I used to know. I can't think the way I used to. Seems like I should know that. I feel like I can't think.") and a fear of punishment (e.g. comprehension items 3 and 8 respectively. "I'd get in trouble and really get it. Otherwise they'd be punished").

The fourth level of behavior was characterized also by passive aggression and impulsivity but feelings of impotence and the fear of punishment were expanded to include general avoidance behaviors (e.g. arithmetic item 9. "I just don't want to think", vocabulary item 8. "That word scares me. I don't know why. similarities item 10. "I don't understand anything the words don't seem right").

Levels of behavior 5 and 6 reflected fewer signs of interference. However this level reflected more direct aggression (e.g.

"How the hell should I know"      n habous corpus is a murdered guy      Hara kiri is like brass knuckles      ") and personalized associations (e.g., similarities 10 "A poem and a statue they tried to learn me", comprehension item 7 "If I was lost I'd tear all the trees apart", vocabulary items 23 and 25 "A vesper is a stick to keep kids in line      recede means getting drunk and never coming home")

It appears that major interferences include passive aggression and impulsivity at nearly all levels, and a perseverative stimulus repetition at level of behavior 1. Feelings of impotence and a fear of punishment appeared at levels 2 and 3. Generalized avoidance behaviors appeared at level 4, and levels 5 and 6 were comparatively free of interference except for some direct aggression and personalized associations. It seems that different levels of behavior give rise to characteristic kinds of interference.

### SUMMARY AND CONCLUSIONS

A patient was reported whose measured (standard) Wechsler Bellevue Intelligence Scale I Q scores were verbal, 59, performance, 43, and full scale I Q, 47, all scores falling in the mentally deficient classification. A learning theory approach to the concept of "potential intelligence" was summarized, and some methods of measuring potential intelligence briefly described. The purpose of the report was to illustrate how obtaining an index of potential intelligence offered the following clinical hypotheses:

- 1 The patient's verbal I Q of 59 probably is not representative of his earlier, presymptom level of functioning.
- 2 He probably functioned earlier at the dull normal or average range.
- 3 At lower levels of behavior (i.e., "latent" or "less available") he shows a greater variability of skills and abilities.
- 4 Whatever skills and abilities are tapped by the similarities subtest appear to be "available" and potentially high, but unexpressed at present.
- 5 Although this patient is presently functioning in the mentally deficient range, he is not a true defective in that a higher level of intellectual functioning is "available," and he probably did not function in the mentally deficient range in the past.
- 6 Responses to learning situations are available at a dull normal or possible normal level. In comparison with patients of identical standard I Q but lower potential I Q, this patient would respond "better" to learning situations.

7 The deterioration index, the measurement of intellectual attitude" and the potential intelligence score seem to give rise to different clinical hypotheses

8 A high degree of interference seems to be operating

9 A higher level of intellectual functioning (in the dull normal or average range) is moderately accessible or available

10 Major interfering factors at all levels include impulsivity and passive aggression. A perseverative stimulus repetition is observable. At intermediate levels of behavior new interfering factors appear: feelings of impotence, a fear of punishment and generalized avoidance behaviors. Still lower levels of behavior give rise to direct aggression and personalized associations as interferences.

This case illustrated how clinical hypotheses regarding a single patient may be derived from some general principles. Further research is needed to test the usefulness of potential intelligence analysis by testing clinical hypotheses which can be obtained by such an analysis.

### HYPERTENSION AND HEMATEMESIS

**Summary of Clinical History** A 40 year old, fairly well developed white man was admitted to the hospital on 16 January 1952 with a chief complaint of pain along the lateral aspect of the right thigh since 15 November 1951, following a skin graft from the right thigh to the left ankle for a burn of the left ankle. The patient had been known to have hypertension for the previous five years, but it had never been evaluated. Three months prior to admission he noted headaches, blurred vision, spots before the eyes, mild exertional dyspnea, weakness, and intermittent disorientation. Six days prior to admission he had shortness of breath on exertion lasting five minutes, accompanied by a regular type of palpitation. He denied dyspnea at rest, orthopnea, wheezing, asthma, chest pains, and pedal edema. The patient had a slight nonproductive cough of two weeks' duration, but denied having hemoptysis. The only urinary symptom was nocturia, two times per night.

Eight months prior to admission, the patient had occasional vague abdominal pain. A gastro intestinal series at that time revealed no abnormalities. Otherwise, his past history was negative.

---

Col James G Moore USAF (MC) Commander From the Medical Service Capt Lee S Monroe USAF (MC) Chief

His father died at age 65 with "kidney trouble" and his mother died at age 73 with "high blood pressure." Four siblings were living and well. There was no known history of diabetes, cancer, tuberculosis, or lung or blood disease in his family.

**Physical Examination.** The patient was a slightly emaciated man appearing 15 years older than his stated age of 40 years. Blood pressure was 240/170 mm Hg, temperature 98°F, pulse 80/min.

Funduscopic examination revealed some increase in light reflex of the arterioles with definite A/V nicking and one patch of white exudate in the right retina. Disk margins were sharp. The trachea was in the midline. The chest was slightly increased in posteroanterior diameter. The cardiac rate and rhythm were regular. The pulmonic second sound equaled the aortic second sound. In the sitting position there was a harsh early systolic grade 2 apical murmur; this was less intense in the recumbent position. The lungs were clear to percussion and auscultation, but breath sounds were slightly distant. The abdomen was concave, soft, and nontender. No masses or viscera were palpable. No costovertebral angle tenderness was present. Examination of the peripheral vessels revealed no evidence of sclerosis or varicosities, and no peripheral edema was present. The skin was clear and slightly dry.

Neurologic examination revealed cranial nerves to be grossly intact; there was no marked deviation from normal in reflexes. All modalities of peripheral sensation were intact and equal bilaterally. Vasomotor lability was demonstrated by marked cold hyperhidrosis.

**Laboratory Studies.** Hemoglobin was 14 g/100 ml, hematocrit 48 ml/100 ml, erythrocyte sedimentation rate 31 mm/hour, and white blood cell count 9,400/ $\mu$ l, with a normal differential count. Bleeding time was 5 minutes, 50 seconds; coagulation time 5 minutes, 5 seconds. The VDRL test was negative. Urinalysis was normal except for 2+ albumin; urine concentration test showed a specific gravity of 1.020 with volume of 260 ml; phenolsulfonphthalein test showed 55 per cent dye excretion in 50 minutes. Blood chemistry was as follows: uric acid 2.8 mg/100 ml, plasma lipid phosphorus 13 mg/100 ml, nonprotein nitrogen 40 mg/100 ml and 33 mg/100 ml, glucose (fasting), 97 mg/100 ml, total cholesterol 245 mg/100 ml, serum sodium 147 meq/l, serum chloride 105 meq/l, serum potassium 4.4 meq/l, total serum protein 6.7 g/100 ml. Vital capacity was 97 per cent of normal. Piperoxan hydrochloride test with 17 mg of Benodaine Hydrochloride: initial blood pressure 195/145 mm Hg, final blood pressure 220/160 mm Hg; hyperventilation test, initial blood pressure 220/110 mm Hg, final blood pressure 210/160 mm Hg.

On 18 January, an intravenous pyelogram showed a normal excretory pattern in both kidneys, pelvis and calyces were normal. A roentgenogram of the chest showed a fracture of the 9th rib posteriorly on the left and of the 9th and 10th ribs posteriorly on the right, but these did not appear to be recent. There was a calcified lesion in the 7th interspace on the right surrounded by a zone of reaction. The heart was within normal limits.

An electrocardiogram on 30 January showed an abnormal pattern in RS T and T waves, which probably represented coronary insufficiency superimposed on left ventricular hypertrophy.

**Course in Hospital.** The patient was placed on a Brompton's diet, after it was established that good kidney function was present. The blood pressure dropped to 180/110 mm Hg on medical treatment. On 8 February, a sympathectomy was done on the right side, from D 5 to L-2, and the patient did well postoperatively. The blood pressure came down to 140/95 mm Hg, but gradually rose again so that by March it was ranging from 200/175 to 120/100 mm Hg. Laboratory studies during this postoperative period showed that the hemoglobin was 12 g/100 ml, hematocrit, 39 ml/100 ml, erythrocyte sedimentation rate, 35 mm/hour, and leukocyte count, 7,300/ $\mu$ l, with 70 per cent neutrophils, 20 per cent lymphocytes, 6 per cent eosinophils, and 4 per cent monocytes. Bleeding time was 2 minutes, 15 seconds, coagulation time, 5 minutes. Urinalyses were negative. Total protein was 6.06 g/100 ml (albumin, 4.48 g/100 ml, globulin, 1.58 g/100 ml), and albumin globulin ratio, 2.83.

Roentgenograms of the chest from 10 to 27 February showed the following. On 10 February a pneumothorax space overlying the right upper lung field was present. There was also some postoperative reaction about the left lower lung field. On 12 February there was some decrease in the pneumothorax space on the right, and the right lower lobe still appeared to be collapsed. Fluid was present in the right side of the chest. On 19 February the previously described collapse of the right lower lobe was more posterior in the chest, and most likely was an empyema along the paravertebral gutter. Fluid from the retropleural space was negative on smear and culture. A lateral study showed some depression of the right middle lobe fissure, some partial atelectasis possibly was present in the right upper lobe. On 27 February obliteration of the pneumothorax space on the right had occurred, leaving some residual pleural thickening. The left lung was clear.

An electrocardiogram on 9 February again showed left ventricular hypertrophy. The RS T wave depression in  $V_1$  and  $V_2$  had

increased, and possibly represented myocardial subendocardial ischemia.

On 4 March, a sympathectomy was done on the left side, from D 4 to D 12. Convalescence was satisfactory. Postoperatively on 4 March the erythrocyte count was 4 920 000/ $\mu$ l, hemoglobin 12.5 g/100 ml and hematocrit 41 ml/100 ml. The urine was normal. Postoperatively the blood pressure ranged from 135/78 to 125/72 mm Hg. A roentgenogram on 5 March revealed clear lung fields and no pneumothorax; one on 10 March showed a pneumothorax over the left upper lung field. Continued absorption of the retropleural fluid on the right had occurred.

On 15 March the hemoglobin was 13 g/100 ml, and blood pressure was 168/90 mm Hg. However, the next day the patient vomited bloody fluid and the gastric contents were positive for blood. The hemoglobin dropped to 5 g/100 ml and the erythrocyte count to 1 260 000/ $\mu$ l. The total serum protein was 6.1 g/100 ml (albumin 4.0 g/100 ml, globulin 2.1 g/100 ml) with an albumin-globulin ratio of 1.9. Despite repeated transfusions—from one to three daily—hemoglobin remained at from 5 to 7 g/100 ml. Blood pressure dropped to an average of 110/76 mm Hg.

A roentgenogram of the chest on 17 March showed considerable reduction in the amount of pleural fluid over the left lung field; however, some fluid remained at the left base. Continuing diminution in the amount of retropleural fluid on the right was noted.

On 18 March the patient had a syncopal attack when he arose to go to the bathroom. He was sweating profusely, appeared weak and complained of chest pain on the left side. Blood pressure was 80/0 mm Hg, pulse 100/minute and respirations 26/minute. Physical examination at that time revealed breath sounds present throughout the lungs with no marked hyperresonance and no evidence of cardiac shift.

On 19 March laboratory studies showed that the hemoglobin was 5 g/100 ml, erythrocyte count, 1 720 000/ $\mu$ l, leukocyte count 16 200/ $\mu$ l with 87 per cent neutrophils, 5 per cent lymphocytes, 4 per cent stab cells and 4 per cent monocytes. The urine was yellow, clear and acid with a specific gravity of 1.010 and was negative for albumin, sugar and acetone. Microscopically there were 2 white blood cells per high power field. The electrocardiogram remained abnormal, however, since the previous tracing the RST and T waves in aVF and left precordium had returned to a more normal configuration.

On 20 March blood pressure ranged around 70/0 mm Hg; pulse was 150/minute and of weak quality. The patient had no pain but complained of "fullness in the stomach" and weakness and

was perspiring profusely. He remained afebrile. Physical examination at 0330 hours revealed a cold, clammy skin, and palpation of the abdomen revealed periodic rushes of peristalsis with associated nausea. By 0500 blood pressure had risen to 110/70 mm Hg and pulse had dropped to 122/minute.

At 2400 on 21 March, the patient went into deep shock and was given blood transfusions, Neo Symphrino Hydrochloride (brand of phenylephrine hydrochloride), and positive pressure oxygen to no avail. The patient died at 0520 on 22 March.

### DISCUSSION

Doctor Abbot: The electrocardiogram showed left ventricular hypertrophy. After his work up it was believed that the man had a malignant or premalignant type of essential hypertension, and he was prepared for sympathectomy. He was put on a Kempner's rice diet and his blood pressure came down somewhat. He had a two stage thoracolumbar sympathectomy, the first from D 5 through L 2, on 8 February. He had what I would assume to be the usual postoperative course with some fluid in his chest and some pain. His blood pressure fell transiently and then returned to more or less preoperative levels. He had a similar operation on the other side on 4 March, about a month later, and his immediate postoperative course was again relatively uncomplicated. His blood pressure came down to normotensive levels and remained there. Electrocardiograms taken during these postoperative periods were said to show changes consistent with myocardial ischemia. According to the nurse's notes, he complained of anterior chest pain at times. It is hard to evaluate chest pain in someone who has had extensive procedures of this type, however, and I don't know that you can attach any significance to it. In any case, the electrocardiograms didn't show signs of recent myocardial infarction.

He first began to vomit dark brown material on 15 March. Not too much stress was laid on that fact. He was nauseated from time to time and complained of some abdominal pain, but this wasn't a frequent complaint and he complained more of chest pain than of the other things. On 16 March he vomited at least 1,000 ml and probably a little more of coffee ground like material. His hemoglobin dropped dramatically—from 13 g/100 ml on the 15th, which would be the first day he began to vomit coffee ground material, to 5 g/100 ml on the 16th—and thereafter it never was normal, although he got several transfusions. Whenever he got up he would have profuse sweating, a rapid pulse, and syncope. He complained of anterior chest pain rather acutely on 17 March and also of pain in his stomach. However, over the next two days he felt better. On 21 March, seven days after he first began to vomit coffee ground material, he had stools described as tarry and red. He went into

---

Capt. Frank K. Abbot, USAF (MC), Assistant Chief Medical Service

syncope with a blood pressure of 80/0 mm Hg. In spite of Neo-Cy nephrine Hydrochloride and blood transfusions he died fairly promptly.

Interestingly enough, gastro-intestinal bleeding after a neurosurgical procedure is not a rare thing. Most of these procedures are ones that involve the brain in one way or another and have been thought in the series that I have seen to be concerned with the specific production of perhaps vagal stimulation along the lines Cushing first laid down causing peptic ulceration. I don't believe that this particular case falls into this category at all. I think we have to look back and think more seriously about his previous history of gastro-intestinal symptoms eight months earlier. These were vague stomach pains of such a degree that a gastro-intestinal series was done. What does one gastro-intestinal series mean? We all know that sometimes quite large significant lesions can be missed on one gastro-intestinal series.

Statistically, the most probable lesion would be a duodenal ulcer however. Of lesions causing bleeding or pain that is the easiest to demonstrate by x ray examination. Gastric ulcer is a possibility. Gastric cancer is a possibility. Hiatus hernia could certainly be present and missed. It could be missed on two or three gastro-intestinal series and to be found after the fluoroscopist thinks about it and tries very hard to find it by various maneuvers of the gastro-intestinal series. Hold that in mind and then try to consider what has happened here. With a bilateral sympathectomy there is sensory denervation of the upper gastro-intestinal tract. Some of the men who began doing splanchnicectomies and more extensive sympathectomy procedures found early that people who had duodenal ulcers didn't get better although they stopped having pain. The ulcers got worse and there are numbers of cases of perforation and perforation in the postoperative period without pain. There are also on record a gradually accumulating series of cases of patients who have not had pre-existing gastro-intestinal complaints but who in a period following either extensive operative procedures or a severe illness will have ulceration and bleeding in the gastro-intestinal tract and this has been thought of as an adaptation breakdown type of disease. Curling's ulcer may be this type of thing and certainly rather extensive erosive mucosal lesions have been found in the esophagus, stomach, duodenum, small bowel and even large bowel in this type of case. That however is certainly more rare.

To my mind the important thing in this case is that a patient after sympathectomy can have a serious bleeding lesion in the gastro-intestinal tract which can be missed. I think that what killed this man was probably a peptic ulcer most likely in the duodenum. Hiatus hernia might be considered as a second choice and with this type of stress gastro-intestinal erosion as a poor third.

Something else found by physiologists is an increase in gastric motility and probably of acid secretion after sympathectomy. This

plus the stress of the operation, activated the ulcer, causing it to bleed. The bleeding was somewhat masked by the syncope which occurs after a bilateral sympathectomy. Not enough significance was laid to it and the patient had no pain to localize it. In the terminal situation I think he was in irreversible shock. I think it is highly likely that he had myocardial ischemia. He may even have had myocardial infarction precipitated by shock for arteriosclerosis is usually considerable in people who are hypertensive.

Doctor Ginsberg: My feeling about the hypertension in this patient is that it was adequately studied and that the patient had hypertensive cardiovascular disease for which sympathectomy is justifiable. The effects of the sympathectomy on this patient's subsequent course would in my mind be in effect this. He had a denervated upper abdomen at least. His left sympathectomy was incomplete but this is routinely done by many surgeons in an attempt to prevent impotence in a male. We can at least say that he was partially denervated as far as abdominal visceral sensation was concerned, but probably not high enough to denervate his coronary blood supply, so that if he had had a severe coronary thrombosis we probably would have known about it. The phenolsulfonphthalein test was 55 per cent in 50 minutes, so we can document good kidney function even in the presence of such severe hypertensive disease that sympathectomy was justified.

The review of the possible sources of the bleeding is entirely consistent with my own opinions. The only other possibility in my mind is that this man's hypertension, his initial finding and his subsequent hemorrhage were due to some disease of the major blood vessels with a vascular enteric fistula. We have to my mind evidence of something occurring in the upper retroperitoneal or lower retropleural or mediastinal area. This possibility is further suggested by palpable pulses on examination, plus the pain that was the man's initial complaint. He had pain in the anterior part of the thigh which suggests the possibility of occlusive disease of the terminal aorta—perhaps aneurysm with rupture. That is the reason I went into some detail about how much bleeding from this man's gastro-intestinal tract had occurred. It is very unlikely that despite multiple transfusions a man can bleed enough to reduce his hemoglobin from 13 to 5 g/100 ml without losing more blood through his colon. I would say that this suggests that he may have been depositing a considerable part of it in his retroperitoneal area or mediastinum. Therefore in my differential diagnosis I would say that the first likelihood would be peptic ulceration—either in the duodenum or stomach or perhaps in the esophagus. Certainly an occult carcinoma of the stomach, diaphragmatic hernia, or severe gastritis could have caused the hemorrhage. Then there are such exotic disorders as lymphosarcoma of the gastro-intestinal tract and occult carcinoma

of the colon and I would like to include in my differential diagnosis aneurysmal rupture of a major blood vessel probably the aorta

Dr. Abbot's diagnoses

- 1 Peptic ulcer in duodenum
- 2 Myocardial infarction
- 3 Arteriosclerosis

Dr. Ginsberg's diagnoses

- 1 Hypertensive cardiovascular disease
- 2 Peptic ulceration in duodenum, stomach, or esophagus
- 3 Ruptured abdominal aortic aneurysm

#### PATHOLOGIC FINDINGS

Doctor Schoffer: This 110 pound somewhat emaciated man had well healed scars in both flanks and a stab wound in the left chest for drainage purposes. When the abdomen was opened the liver was approximately 7 cm below the costal margin. The stomach was markedly dilated. The left side of the chest had some fibrous adhesions and a thick layer of fibrin around the pleural surfaces particularly in the left lower lobe. The right side of the chest had a hematoma in it as was noticed on the x rays and it contained approximately 250 ml of old clotted blood.

The heart weighed 459 grams. The coronary arteries showed very severe arteriosclerosis and very marked narrowing of the lumina particularly of the right coronary which had practically a complete occlusion grossly. Microscopically there were a few recanalized channels through an old organized thrombus. The left anterior descending and left circumflex arteries showed very severe narrowing. There was a 1.5-cm fibrous scar on the apex. In the anterior portion of the septum there was a 2 cm area of discoloration. Microscopically this area showed a few polymorphonuclear leukocytes and lymphocytes scattered between the fibers. The fibers showed evidence of early acute degenerative change. There was loss of striations with beginning hyalinization and some of the nuclei were beginning to fade out.

The aorta showed very little atherosclerosis with only a few plaques scattered throughout and practically no calcification. No aneurysm was found.

The lungs were somewhat heavy. The right weighed 560 grams the left 665 grams. The lower lobes on both sides had some increased firmness suggestive of mild pneumonia. There were fibrous and fibrous adhesions noted on both sides.

The liver weighed 2,000 grams which is very sizable. There was a somewhat accentuated lobular architecture. Microscopically there

as central lobular congestion and mild lymphocytic infiltration in the portal areas

The kidneys were of normal size, the capsules stripped easily and the surfaces were fairly smooth. Microscopically, there was mild arteriosclerosis.

The brain had a normal architecture throughout except in the right temporal lobe where there was a 2 by 3 cm area of old hemorrhage with old dark, somewhat clotted blood.

The gastro-intestinal tract was filled throughout with large quantities of clotted and fluid blood. The stomach contained 3 000 ml of clotted and fluid blood. There was a 9 cm ulceration on the posterior wall of the stomach in the prepyloric area, the edges were slightly raised. In the base of the ulcer there was a 3 mm artery whose lumen was open and projecting into the base of the ulcer. This was dissected out and found to be the right gastropyloric artery. Microscopically there was considerable collagenous scarring in the base of the ulcer. The small intestine contained large quantities of dark red blood. The large bowel contained black, thick pasty material.

In summary this was a hypertensive middle-aged man who had had a bilateral sympathectomy. Postoperatively a chronic ulcer broke down, and further ulceration penetrated his gastropyloric artery, causing him to bleed to death. Along with that he had severe atherosclerosis and coronary insufficiency which with anemia and shock led to early myocardial infarction. He had a small hemorrhage in his brain that produced transient symptoms.

#### Pathologic diagnoses

- 1 Hypertension
- 2 Chronic gastric ulcer of prepyloric area, with penetration of gastropyloric artery
- 3 Atherosclerosis and coronary insufficiency
- 4 Myocardial infarction
- 5 Intracerebral hemorrhage

Doctor Monroe: The problem of whether to do a sympathectomy upon a hypertensive patient is at this time I believe, in a different category than it was when this operation was performed. Now we have certain medications, namely the derivatives of rauwolfia—the reserpine that was isolated by CIBA—and our ganglionic blockers as demonstrated by Ansofysen Tartrate (brand of pentolinum tartrate) which perform a medical sympathectomy rather efficiently, thus we are able to handle a case of even malignant hypertension probably as adequately as the surgeon. This is no criticism of course, as these drugs were not on hand at the time this procedure was done. At the present time I cannot think of any patient with essential hypertension whom I would refer for sympathectomy. I realize that there is a great deal of opinion to the

contrary but certainly I believe that as we accumulate data on these drugs sympathectomy will fall into disuse

Doctor Tyson There are a few comments I would like to make with reference to the management of both hypertension and upper gastrointestinal bleeding First of all a sympathectomy an extensive sympathectomy for hypertension was first done a little over 20 years ago Several years ago it was quite popular in the treatment of hypertension especially in those cases that did not respond favorably to medical management Hypertension has been classified roughly in four groups In group 1 are patients with mild hypertension who can be treated very satisfactorily medically In groups 2 and 3 are patients who do not respond to medical management I feel that three or four years ago a sympathectomy was indicated for these patients In group 4 are those patients with a fixed blood pressure especially those with kidney damage and a high nonprotein nitrogen I think a sympathectomy for the patients in group 4 was in most instances contraindicated Thus the patient would most probably fall into group 2 or perhaps in group 3 So I feel definitely that in 1952 the sympathectomy on this patient was in order

It has been emphasized that ulcers sometimes appear to be worse following sympathectomy Three or four years ago the Mayo Clinic reported a series of about 900 cases of thoracolumbar sympathectomy In 20 of these ulcer symptoms were manifested in the early postoperative period About 17 of these had had previous ulcer symptoms The authors could not conclude that this was significant and they could not draw any definite conclusions that sympathectomies do make ulcers worse but it seems to be the general consensus that such is the case In my limited experience I have had occasion to see two patients bleed from ulcers following sympathectomy As far as the results of sympathectomy for hypertension are concerned it is difficult to find any statistics to go by but after five years approximately 60 per cent of the patients in group 2 and about 20 per cent of the patients in group 3 have a significant reduction in blood pressure I believe most authorities agree that the survival time of these patients is probably increased by sympathectomy As Doctor Monroe has mentioned within the past three years newer drugs have been developed which are very effective I personally haven't seen a sympathectomy done in three years and don't care to do them I think that for the most part it is a poor way of treating hypertension Another surgical method of treating hypertension is adrenalectomy Experimental work has been done on this problem in a good many places I personally at the University of Tennessee operated on a number of dogs in which experimental hypertension was produced using Goldblatt's clamp Total adrenalectomy was then performed and the dogs maintained on cortisone We found that we could

keep the blood pressure down for many months sometimes more or less permanently, by this method. Subtotal and total adrenalectomy have been advocated in some centers for rapidly progressive cases of malignant hypertension. Doctor Bowers<sup>2</sup> at the Veterans Administration Hospital in Memphis has done a number of subtotal adrenalectomies on patients with severe malignant hypertension and seems pretty enthusiastic about it. It does seem to prolong life and to alleviate the symptoms in patients who survive the procedure.

Curiously enough following sympathectomy many patients will feel better subjectively. Their headaches, dizziness, chest pain, shortness of breath, and other symptoms of hypertension will often regress even though the blood pressure may go back up after a few weeks or months. Another fact that might be mentioned is that following sympathectomy those patients who have previously been resistant to medical treatment seem to respond better to medical treatment.

## SERVICE ARTICLES

# EFFECTS OF SEDATION ON AIRBORNE PSYCHIATRIC PATIENTS

FRANKLIN H. ERNST JR. M.D.

**P**SYCHIATRIC patients often present management problems in flight, and if they become assaultive can be sources of danger to the other occupants of an aircraft. The flight nurse frequently wonders whether or not certain of the patients should be resedated if so at what stage. In order to determine what our sedation was doing for the large numbers of closed-wing psychiatric patients being flown out of this base to formulate criteria for resedation and to compare the relative merits of amobarbital and phenobarbital, a study was carried out during the 12 months ending on 30 April 1953. It was thought that perhaps the effects of sedation might be improved by changing the medication from 0.4 gram of amobarbital sodium by mouth to 0.3 gram of phenobarbital sodium in glycerin intramuscularly.

All patients evacuated by air from the Pacific area and many of those from Alaska were routed through this base on their way to military hospitals on the eastern seaboard. Patients studied were those classified either as 1A needing both sedation and restraint, or as 1B needing either sedation or restraint, when airborne. In practice, this hospital routinely sent even 1B's in a chemically and physically restrained condition.

### METHOD

Every other patient to be transported by air was given amobarbital sodium by mouth and the alternates received phenobarbital sodium intramuscularly, in the dosages mentioned. Three patients who would not take amobarbital orally received 0.5 gram of the aqueous preparation intravenously.

Questionnaires were attached to the flight tag of each patient stating (1) name (2) medication prescribed and (3) time administered. The flight nurse was asked to describe the sedative effect on the patient during the trip, report the amount, type, and time of any resedation required, sign her name, and return the tag to this base.

---

From U. S. Air Force Hospital, Tyndall Air Force Base, Calif. Dr. Ernst is now at 408 Tennessee St., Vallejo, Calif.

## RESULTS

Of the 1,219 questionnaires sent out with sedated patients for whom there were complete medical records, 625 (51.3 per cent) were returned. Of these, 329 pertained to patients who had received amobarbital and 296 to those sedated with phenobarbital. The duration of flight for 460 of the patients was from 8 to 12 hours and for 152 was from 4 to 6 hours. For 14 it was only about 2 hours.

In going over the individual reports, there seemed to be three broad categories into which the responses fell. The effect of medication was such that during the trip the patient presented (1) no nursing problem, (2) some problems, or (3) serious problems. The first group were quiet and cooperative, and were either asleep or dozing at intervals. A few slept or were sedated throughout the flight. The second group were restless, talkative, agitated, boisterous, or sullen and withdrawn, but in any case could be reasoned with. The third group presented serious and even dangerous problems, being hallucinated, overactive, unsalvageable, or suicidal.

As shown in table 1, there was a slight though not statistically significant difference in the response of patients sedated before flight with phenobarbital sodium as compared with those sedated with amobarbital sodium. With phenobarbital, 85.6 per cent were no problem and 11.5 per cent presented minor problems, with amobarbital, the percentages were 90.6 and 7.0, respectively.

TABLE 1 Percentage of patients presenting nursing problems after sedation with amobarbital sodium (A) or phenobarbital sodium (P) by length of flight

Response to medication	Length of flight (hours)						Total of all flights		Total combined A or P
	2		4-6		8-12				
	A	P	A	P	A	P	A	P	
No problem	100.0	40.0	91.4	87.9	87.9	85.3	90.6	85.8	88.1
Slight problem		40.0	7.5	10.4	7.0	11.1	7.0	11.5	9.1
Serious problem		20.0	1.1	1.7	3.1	2.6	2.4	3.9	2.8
Total number	6	8	12	12	12	12	12	12	6

after phenobarbital would be an advantage in the event of ditching on an overwater flight. In such case, the amount of drowsiness present and the degree of reality orientation of patients would be of importance, and phenobarbital did leave a larger percentage of patients alert than did amobarbital (49 per cent versus 33 per cent).

It can be seen from table 1 that taking both groups together, more than 88 per cent of the patients were no problem whatsoever to the flight nurse, while 9 per cent caused some trouble and between 2 and 3 per cent presented serious problems in management. The 9 per cent of patients who presented minor nursing problems because of being agitated, apprehensive or boisterous were the group with which expert handling could produce the most benefit by keeping them from becoming more active thereby preventing trauma to these restrained patients under the stress of flying.

The 2 to 3 per cent of patients who posed serious nursing problems are presented in more detail in table 2. Out of 623 closed ward psychiatric patients only 16 (1 in 39) became an important nursing problem on board an aircraft. Of these, there were 6 (1 in 104) who were assaultive combative or suicidal and therefore physically dangerous to themselves or other patients or members of the crew. Each of these 6 patients had a previous history of similar difficulties. None of the small number of patients on 2 hour flights showed this dangerous response but on 4 to 6-hour flights it was 1 in 152 and on 8 to 12 hour flights 1 in 92 (5 in 460).

TABLE 2 Breakdown of serious nursing problem group of patients

Response to medication	Length of flight (hours)						Total of flights	
	2		4-6		8-12			
	Number	Percent	Number	Percent	Number	Percent	Number	Percent
Hallucinated, overstimulated	1	7.6			6	1.3	7	1.1
Resistive, profane			1	0.7	2	0.4	3	0.5
Assaultive, suicidal			1	0.7	5	1.1	6	1.0
Number of patients	13		152		460		625	

Sedation was mainly limited to long flights. On those lasting 8 to 12 hours 39 of 460 patients (1 in 12) were resedated whereas none of the 13 patients on 2 hour flights received additional sedation and only 4 patients in 152 (1 in 38) on 4 to 6-hour

flights received it. The 17 patients who were re-sedated in spite of presenting no nursing problem had either complained of body aches or were awake during the long trip and asked for more sedation. The remaining 26 needed it for various psychiatric reasons, 9 being serious management problems and 17 presenting minor nursing problems (table 3).

TABLE 3 Number of patients re-sedated

Nursing problem	4-6 hour flights				8-12 hour flights			
	Amobarbital		Phenobarbital		Amobarbital		Phenobarbital	
	Number	Number re-sedated	Number	Number re-sedated	Number	Number re-sedated	Number	Number re-sedated
None	86	2	51	1	204	8	201	6
Some	7		6		16	7	26	10
Serious	1		1	1	7	5	6	3
Total	94	2	58	2	227	20	233	19

It appears that on a long flight, if a patient has a history on the flight tag of assaultiveness, re-sedation should be seriously considered about 3 to 4 hours after the initial medication was given. Flight nurses might properly have little fear of over-sedating by the intramuscular route on overactive patients. Re-sedation can be considered as early as 2 hours after the initial medication is given, especially if the patient is *well hydrated*. However, it should be borne in mind that *dehydrated* patients may accumulate the intramuscular medication in their tissues without its being picked up by the circulation and having an observable effect until many hours later, when it might be overwhelming in amount.

### SUMMARY

No statistically significant difference was observed between the sedative effect of oral amobarbital on 329 airborne psychiatric patients and that of intramuscular phenobarbital on 296 patients.

Of the two groups combined, only 2.6 per cent posed serious management problems and only 1.0 per cent were assaultive or suicidal. The percentage of patients presenting serious nursing problems increased with length of flight.

Re-sedation should be seriously considered on any long flight for a patient with a history of assaultiveness.

# PREVENTIVE DENTISTRY IN THE U S AIR FORCE

FRANCIS J SAMAHA *Major USAF (DC)*

**T**HE SIGNIFICANCE of preventive measures in dentistry, as in medicine and industry, cannot be overemphasized.<sup>1</sup> The Air Force dental service is dedicated to the preservation of dental and oral health by the prevention and treatment of dental and oral diseases and injuries among military personnel. For effectiveness, prevention must be foremost in the mission. Inductees are in the age group having the highest rate of dental caries and requiring extensive oral rehabilitation.<sup>2,3</sup> The military, with its organization and records system, affords an excellent opportunity for establishing a closely monitored dental program which permits instruction in oral hygiene and effective follow through in the maintenance of oral health.

## PREVENTIVE DENTISTRY PROGRAM

A plan designed by the dental service of the United States Air Force (Section G AFM 160 13) was put into effect in October 1952 to supplement the oral rehabilitation services of modern dentistry.<sup>4,5</sup> As developed at this Air Force base the plan includes both education and prophylaxis.

### Education

Dental health lectures employing illustrative clinical color slides are presented to all base units annually with the new Air Force training films entitled "Preventive Dentistry" planned for showing. Descriptive literature and personal instructions on proper oral hygiene are given to patients during their oral prophylaxis treatment. New posters developed locally are displayed at intervals in prominent locations throughout the base. The educational material used in this program was developed according to the criteria for acceptability set forth by the American Dental Association<sup>6</sup> which state that it (1) must be authentic, (2) must meet existing needs, (3) must be effective in promoting dental health and (4) must be suitable for various age groups and intellectual levels.

---

From U S Air Force Hospital Bergstrom Air Force Base Tex. Dr Samaha now  
Tufts University School of Dental Medicine Boston Mass.

### Oral Prophylaxis

One of the primary objectives of the Air Force Preventive Dentistry Program is to accomplish at least one annual oral prophylaxis on all personnel. This in effect means that about 9 per cent of the men at each base must receive oral prophylaxis each month. This is accomplished by the following procedures:

1. All persons appearing on dental sick call who have not had an annual prophylaxis are immediately given an appointment.

2. A review of the A F Form 309 (Dental Health Records) is made periodically for more effective control of this annual requirement.

### DIAGNOSIS AND TREATMENT

Early diagnosis and treatment are essential elements in a preventive dentistry program. It is important to note that many of those persons who have requested a dental examination have asymptomatic gingival or periodontal disease and/or carious lesions of which they were unaware.

When diagnosis has been established, the dental status of military personnel is determined by the official dental classification system of the Department of Defense. This dental classification system is outlined as follows:

*Class 1* Individuals requiring no dental treatment.

*Class 2* Individuals requiring routine but not early treatment of such conditions as (a) moderate dental calculus, (b) prosthetic conditions not included in class 4, (c) caries (not extensive or advanced), (d) periodontal diseases (not extensive or advanced), and (e) those requiring corrective or preventive measures.

*Class 3* Individuals requiring early treatment of such conditions as (a) extensive or advanced caries, (b) extensive or advanced periodontal diseases, (c) pulpal or apical infection, (d) chronic oral infections, (e) heavy dental calculus, and (f) those requiring removal of one or more teeth or other surgical procedures not included in class 5.

*Class 4* Individuals requiring essential prosthetic appliances, including (a) those with insufficient teeth to masticate the service ration, and (b) others in need of an appliance essential to their duty.

*Class 5* Individuals requiring emergency dental treatment for such conditions as (a) injuries, and (b) acute oral infections (acute parietal and periapical abscesses, Vincent's infection, acute gingivitis, acute stomatitis, et cetera).

The following factors have been important in the implementation of the Preventive Dentistry Program at this base

1 An adequate professional staff is of paramount importance. The average staff ratio at this base during 1955 and until June 1956 was 1.9 dental officers per 1 000 military personnel. This compares favorably with the staffing ratio requirement of 3.9 dental officers per 1 000 military personnel.

2 Equally important is the base regulation regarding dental appointments, so that continuity of service can be maintained. By adhering to this regulation broken appointments have been reduced and the cooperation of base personnel has improved.

3 Continuous surveys are in progress to recognize those patients who are neglecting dental health requirements.

### EFFECTS OF PROGRAM

In order to assess the effects of the Preventive Dentistry Program the dental health status of personnel at this Air Force base for the years 1955 and 1956 were compared with that of the entire Air Force prior to initiation of the program in 1952 (table 1). The figures for Bergstrom in 1952 were not available. Percentages are expressed in terms of the official dental classification system. Before the Preventive Dentistry Program became

TABLE 1 Comparison of dental health status of U S Air Force in 1952 before the oral prophylaxis program, with that of Bergstrom Air Force Base in 1955 and 1956

Group	Year (calendar)	Accumulated oral prophylaxis per month (percentage)	Percentage strength in dental classes				
			1	2	3	4	5
U S Air Force	1952	2.8	34.6	32.9	28.8	2.7	1.0
Bergstrom Air Force Base	1955	8.2	60.9	23.1	13.5	2.5	0.0
	1956 (June)	9.3	65.8	19.6	13.5	1.1	0.0

effective only about a third of Air Force wide personnel were receiving oral prophylaxis each year. At this base in 1955 and the first half of 1956 all military personnel received at least one oral prophylaxis per year. The indication is that implementation of the program leads to a definite increase in the number of men in class 1 and a corresponding decrease in the number in classes 2 through 5.

To further test the program's effectiveness, a careful screening of the 4,319 base dental health records was accomplished. Of these, 1,456 were eliminated because an annual examination was not recorded. On the basis of the dental classification system, the findings of initial examination in 1,079 men, annual examination in 1,723 men, and discharge examination in 61 men were compared. As noted in table 2, there was a 30 per cent increase in class 1 on annual examination as compared with the initial examination, and an additional increase of 31 per cent on discharge, with a corresponding improvement in the other classes.

TABLE 2 Dental classification of personnel at Bergstrom Air Force Base on initial annual and discharge examinations

Group examined	Number of cases	Per cent strength in dental class			
		1	2	3	4
Initially	1 079	23	35	40	2
Annually	1 723	53	30	15	2
On discharge	61	84	15	1	0

The two groups—those examined initially and those examined annually—were compared for the incidence of caries, extractions, and periodontal disease. It was found that the annual group averaged 1.1 dental cavities per man, while the group examined initially averaged 2.4 cavities. Despite the fact that there were 644 more men in the annual group than in the initial group, there were 58 fewer cases of periodontal disease and 225 fewer extractions in the annual group than in the initial group.

### FLUORIDATION OF DRINKING WATER

Today, fluoridation of drinking water is recognized as an effective advance in preventive dentistry. Its practical worth has been adequately demonstrated.<sup>9</sup> However, despite its impressive benefits it is only one of those weapons to be used against oral diseases. All known preventive measures must be employed as parts of a fully organized program.

Official figures of the United States Public Health Service as of September 1956 show that about 1,400 communities in the United States, with a total population of over 30 million, receive the benefit of fluoridated drinking water.<sup>10</sup> Fluoridation is providing constant benefit to those millions.

tremendous reductions in dental caries among children and young adults

On the basis of pertinent research findings regarding the measure of protection for adult teeth the Committee on Dentistry of the National Research Council late in 1953 justified fluoridation at military installations.<sup>1</sup> Since that time, the Air Force has made rapid strides in developing policies, criteria, and program. To date, a total of 25 Air Force bases, including this base have had plans for fluoridation of their drinking water approved. Thus far four bases (not including Bergstrom at this writing) have implemented the program.

Since the Government bears heavy expenses in maintaining dental clinics, equipment, supplies, and professional staffs, the cost of dental care is of great concern.<sup>2,3</sup> It has been stated that the "Department of Defense spends about \$100 million annually for the dental care of military personnel and uses the services of nearly 8,000 dentists in the Armed Forces."<sup>4</sup> However, because of the great potential existing in preventive programs, it will be understood why considerable emphasis is placed on the Air Force Preventive Dentistry Program by the Office of The Surgeon General.

The future for preventive dentistry looks bright. Active preventive dentistry and oral research programs should bring new hope for better control of oral diseases through more effective methods of prevention of those conditions that now afflict almost every person.

were made between growth in media inoculated in the field and in media inoculated in the laboratory later from the same water sample

Accordingly, a coliform kit was devised consisting of 10 six dram (23 by 88 mm) screw capped vials for media and a 250 ml, glass stoppered sample bottle. Five milliliters of a 3% strength lactose broth were placed in five vials, and 5 ml of a 3% strength lauryl tryptose broth were out into the other five vials. The two media were used to see if one would be more efficient for detecting coliform organisms. For chlorinated waters a small amount of sodium thiosulfate was added to the sample bottles. Vials and sample bottles were sterilized by standard methods. Vials were calibrated with a scratch mark at the 15 ml level to facilitate the addition of 10 ml of the sample to the 5 ml of media. The vials were placed in one mailing carton and the sample bottle in another.

An instruction and data sheet was enclosed in each kit with the request that the sample be taken a short time prior to shipping. During cold weather especially if freezing was likely, note was added requesting that the inoculated vials be left overnight in a warm room to encourage bacterial growth before shipping. Upon receipt in the laboratory vials of media showing adequate growth were subjected to the confirmatory test. Those vials which were clear or showed slight turbidity were incubated at 35° to 37°C overnight. If no growth was then evident they were discarded as negative. The remaining portion of the water sample which was returned unrefrigerated with the vials was examined by the standard laboratory test using lactose broth.

Over a period of approximately three years, a total of 907 coliform kits were sent or taken into the field and 169 were returned. Samples were received in the laboratory during all months of the year except March and May, most of them being shipped during the summer and fall.

The area covered in the sampling included the northern and western Alaskan coasts, St. Lawrence Island, lower Foul Bay River (southwestern) and the interior and south central region. Approximately 65 per cent of the samples were from surface supplies.

The inoculation of the media vials in the field was usually accomplished within an hour after collection of the sample. The interval of time between the collection and the laboratory examination of the shipped water samples varied from 6 hours to 10 days with one interval of 14 days. The average time was 4.3 days. Ninety six (56.8 per cent) of the samples showed an

elapsed time of more than 3 days before they were examined in the laboratory

The evaluation of differences was based on the numbers of samples, vials, or tubes which were found to be positive for coliform bacteria. Significant findings were indicated where there were completely negative results on the one hand and positives on the other. No attempt was made to show differences in terms of Most Probable Numbers (MPN).

### RESULTS AND DISCUSSION

Of the 169 samples examined, 96 (56.8 per cent) were positive for coliform bacteria. Samples positive and negative for coliform bacteria by the two procedures are shown in table 1.

TABLE 1 *Results of field and laboratory procedures*

Samples		Results of procedures	
Number	Per cent	Field	Laboratory
73	43.2	-	-
68	40.2	+	+
27	16.0	+	-
1	0.6	-	+

The most noteworthy point in this table is indicated by the 27 samples (16.0 per cent) which were positive by the field procedure but negative by the standard laboratory procedure. According to the latter test, these water samples would have been classified as potable, when actually they were not. There had been either a complete die off of coliform organisms, or a reduction in numbers to the extent that they could not be detected in the shipped samples by the laboratory technique employed. By contrast, the field procedure failed to show these organisms in only one sample (0.6 per cent) in which the laboratory procedure demonstrated their presence.

A comparison of the productivity of the two media inoculated in parallel in the field showed that differences were, for the most part, not significant. Of 95 samples positive for coliform bacteria, 94 (98.9 per cent) were positive in lactose broth, while 89 (93.7 per cent) were positive in lauryl tryptose broth. However, the total number of confirmed lauryl tryptose broth vials exceeded those of the lactose broth by approximately 3.3 per cent.

The increased effectiveness of the procedure is dependent upon the initiation of coliform growth soon after collection of the sample. These organisms are capable of growing over a wide range of temperature, viz., 5° to 45°C, although there is some selectivity as to types which will grow at the extreme temperatures. The effects of non coliform overgrowth and antagonism would be less likely where coliform organisms have had a chance to develop before shipment. Furthermore, these effects could be lessened by using a selective medium such as lauryl tryptone broth.

By using five 10 ml portions of water per sample an estimation of coliform density can be obtained. Under the usual conditions of testing in the field a high degree of accuracy in enumeration is difficult to achieve.

### SUMMARY AND CONCLUSIONS

A simple and effective procedure for determining the potability of water supplies in the field is described. The inoculation of media in the field is a feasible procedure. It is applicable to the bacteriological examination of turbid waters such as often found in samples from surface supplies in rural Alaska. This procedure is believed to be especially adapted to those areas where an inordinate amount of time is required for the sample to reach the laboratory after collection. Furthermore this method gave considerably fewer false negative results than the standard test when performed on shipped, unrefrigerated water samples.

#### KNOW YOUR INDUSTRIAL SOLVENTS

The use of the so called industrial solvents is no longer confined to a plant or factory In various forms they are utilized in the home in the garden and on the farm Rarely are they harmful if handled judiciously A physician should be able to advise his patient what the preventive measures (careful handling) are He should likewise recognize the ear marks of any given intoxication if and when it occurs His treatment should be based upon his knowledge of the expected physiologic and pathologic reaction The physiologic classification of these solvents is therefore very important

—RUTHERFORD T JOHNSTONE M D  
in *Illinois Medical Journal*  
pp 301 302 Nov 1954

1 Below are some reasons given by others as being important as to why they are test pilots. We would like you to rank these as to importance in your case. Place a 1 before the factor you feel is most important, a 2 before the second most important item, a 3 before the third, and so on. Remember to rank them in terms of what is important to you. Your responses will be confidential so please be frank.

- diversified flying (all types or particular types)
- pay (including flight pay)
- prestige—recognition
- rank (chance of promotion)
- thrill (the danger involved)
- desire to conquer and explore unknown areas
- consider it a good stepping stone to a civilian job
- get out of previous unpleasant assignment

2 List three factors which you feel would have better qualified you for your present assignment.

3 Below is a scale indicating possible attitudes toward your assignment as a test pilot. Please place a check above the number that best describes your present feelings toward your assignment as a test pilot.

1	2	3	4	5
Very satisfied enthusiastic about present assignment	Satisfied but not enthusiastic	Indifferent to present assignment no strong feelings either way	Dislike present assignment but do not plan to request change	Strongly dislike present assignment would change if possible

4 Do you feel you are (more or less—circle appropriate word) satisfied with your assignment than the average Air Force Officer?

5 Do you plan to be a test pilot two years from today? Yes—  
No—

## RESULTS

The questionnaire results will be presented first and then amplified by the information obtained in the interview. The reasons for being a test pilot in question 1 were placed in the following order as to importance:

- 1 Diversified flying (all types or particular types)
- 2 Desire to explore and conquer unknown areas
- 3 Prestige—recognition
- 4 A good stepping stone to a civilian job

- 5 Thrill (the danger involved)
- 6 Rank (chance of a promotion)
- 7 Pay (including flight pay)
- 8 Got out of previous unpleasant assignment

Diversified flying was easily the most important reason for being a test pilot. Desire to conquer and explore unknown areas was given as the second most important factor, and prestige-recognition was third. Figure 1 presents the quantified score in graph form for each factor. The score was obtained by giving each 1 response a weight of 8, each 2 response a weight of 7, each 3 response a weight of 6, et cetera. Figure 1 indicates that the first three factors are clearly the most important reasons why these pilots requested test flying. The belief that the thrill and the danger involved are an important motive for becoming a test pilot is not supported by these results. Thrill is fifth in importance, no pilot checked it as either first or second in importance, and only two pilots rated it as third.

Figure 1 Motivation of test pilots.

On question 2 relating to prior experience, 18 of the 21 pilots completing the questionnaire stated that they believed more technical information and more formal schooling, especially in engineering, would have made them better qualified for test flying. Thirteen of the 21 thought that more diversified flying experience would have better qualified them for their present assignments. No other area approached this degree of unanimity.

Seventeen of the 21 pilots stated that they were highly satisfied and enthusiastic about their present assignment, 2 were satisfied, 1 was indifferent, and 1 disliked his assignment. All

but two believed they were more satisfied with their assignment than the average Air Force officer and all but one said they planned to be test pilots two years from today

These results indicate that as a group test pilots are highly satisfied with their present duties and plan to continue being test pilots as long as possible

### INTERVIEW FINDINGS AND DISCUSSION

The results of the interview strongly support the questionnaire finding that the persons in this group were highly satisfied with their duty as test pilots. The love of flying and the chance to fly different types of aircraft were found to be the primary motives and a feeling of accomplishment and of making a significant contribution to the Air Force a close second. Many thought that in peacetime this was the only assignment that offered a challenge and a feeling of self satisfaction. Prestige and recognition as in the questionnaire was about third in importance but interestingly the majority of those interviewed considered that this recognition often came from sources outside the Air Force. Also since desire for diversified flying is such a strong motivating force for becoming a test pilot any curtailment of this opportunity might result in some feelings of disappointment and could contribute to lowered morale.

From this limited sample it appears that there is no one type of personality or socioeducational background that is characteristic of most test pilots. As in other occupations test flying meets different personality needs for each individual. However the common conception of test pilots as carefree happy go lucky devil may care individuals applies only to a very small minority. A few such types seem to be present but they will probably become less numerous as the true scientific nature of the work base becomes more widely known. The test pilots studied at this base are cautious careful individuals whose approach to their task is similar to research workers in other areas. They conceived their mission as one of gathering reliable and accurate information and their behavior in the air and on the ground seems to be guided by this over all goal. The almost unanimous desire for more technical education supports this conception. Perhaps it would not be amiss to refer to them as research pilots rather than test pilots.

Of particular interest in these interviews were the pilots attitudes toward the dangers involved in supersonic flying of relatively unproven aircraft. None denied the existence of these dangers but all thought they would be able to anticipate and prevent mishaps. Of major importance here was their self con-

confidence and their feeling that they knew their aircraft well. The long hours spent studying mock ups and in briefings before actually flying the aircraft seem to greatly reduce the fears of the unknown. A few admitted this overconfidence in their ability might cause them to stay with the plane too long, but each believed he would be able to make the correct decision. Another factor which may cause the pilot to stay with the plane beyond the safe ejection point is the feeling of unreality. Because of their many hours of flying when they have always been able to "bring it back" and their extreme confidence in their own ability, the feeling that this "couldn't be happening to me" may delay the decision to eject beyond the critical point. Few believed they could eject at high speeds and survive, and all thought this factor also might cause them to stay a little longer in an endeavor to control the aircraft. All hoped for improvements in the technique of high speed ejection, most believing that "high speed ejection is something you have to live with today."

### FUTURE ASSIGNMENTS

Assignment after completing his tour at this base is something no test pilot anticipates with any eagerness. Most test pilots seem to consider that this is the top assignment of their career and that any other will be anticlimactic. The type of assignment given them after completing their present tour was often mentioned as the crucial factor as to whether or not they would remain in the Air Force. It seems it is at this point that the lure of civilian test flying may become most attractive.

Two suggestions were offered to prevent this loss of highly skilled personnel to the Air Force. Those with engineering training considered that the logical progression was (1) to project officer and then (2) to a weapons system project officer. Pilots who wanted to return to tactical operations suggested that they follow an aircraft through the test program and then into the field. They thought that they would then be in an excellent position to utilize the experience and knowledge gained during testing. All test pilots felt that the individual pilot should be consulted before any future assignments were made.

### SUMMARY

To study the attitudes and motivations of test pilots assigned to Flight Test Operations at this base, 12 pilots were interviewed and 21 completed an attitude motivation questionnaire. Results indicated that pilots become test pilots primarily because they love to fly, and because they feel they are accomplishing something worthwhile. Prestige and recognition are also important factors, but most test pilots believe this comes pri

marily from sources outside the Air Force. Technical information, engineering training, and diversified flying experience are listed as important prerequisites. The modern test pilot's approach to his work seems to be similar to that of research workers in other areas and the happy carefree devil may care individual seems to be the rare exception rather than the general rule. The term "research pilot" is suggested as a more descriptive term than "test pilot." As a group test pilots are highly confident of their flying ability. This self confidence and thorough knowledge of their duties seem to be important factors in overcoming the fear of the danger involved. For this sample of pilots, the dangers and unknowns of supersonic flight did not appear to pose a problem. Exploring these unknowns is an important motivating force. Most test pilots consider that this type of flight duty is the top Air Force assignment of their career and that any future assignment will be anticlimactic.

#### RESEARCH MONEY

A sharp increase in the volume of medical research and in the funds available for its support have been major developments of the past 10 years. Total national expenditures have increased from 75 million dollars in 1945 to about 240 million dollars in 1955. Each of the major contributors—philanthropy, endowment, industry, and government—increased its total contribution. This is important because diversity in source of support for research is vitally important. However, the increases have not been proportionate. At the present time government supports about half the medical research in this country and industry about a third. Funds from endowment and philanthropy have not increased at a rapid rate.

## Coarctation of the Aorta

With Resistance to Blackout From Acceleration Forces

HENRY A SCHLANG *Commander MC USN*  
ALAN L HASLUP *Lieutenant MC USNR*  
RUFUS J PEARSON Jr *Captain MC USN*

THE DIAGNOSIS of coarctation of the aorta has become so commonplace in large hospitals that a report of a single additional case requires more than the inherent interest in the disease to justify its publication. An aviator with an unusual feature of coarctation was seen recently at this hospital. While giving his history to a physician, the patient stated that he had consistently had an increased resistance to blacking out during flight maneuvers involving acceleration forces ordinarily considered sufficient to produce blackout. A relationship between this resistance and the coarctation warrants consideration of the possible mechanisms.

### CASE REPORT

A 23 year old Marine Corps aviator who had been retired because he had coarctation of the aorta was admitted to this hospital on 13 August 1956 for surgical correction of the coarctation. The past history revealed that in October 1953 when he received a physical examination for appointment to a commissioned grade a cardiac consultation had been obtained because of cardiac murmurs. Apparently the murmurs were considered not disqualifying because he was accepted for active duty. An electrocardiogram of 2 November 1953 had been reported as within normal limits. On 28 May 1954 a physical examination at a naval air station revealed a loud systolic murmur over the pulmonic valve and a soft diastolic murmur to the left of the sternum. Hypertension of moderate degree had been noted on several occasions in the 1953-1955 period.

There were no symptoms referable to the cardiovascular system except for tingling in the legs when the patient was nervous and precordial heaving of several months duration. Throughout his training and career as a Marine Corps aviator he had had an unusual resistance

From U S Naval Hospital, National Naval Medical Center, Bethesda, Md. Comdr Schlang is now assigned to U S Naval Hospital, St Albans, N Y.

to the blacking out effect of acceleration. The patient claimed that at no time during his flight training did he experience blacking out or graying out (loss of peripheral vision). In 1954 while training with AD-1 fighter bombers he made 192 practice bombing runs entailing 40° glide-bombing runs and 60° dive bombing runs. During none of these did he grayout or blackout. He stated that at one time or another during the practice bombing runs every man in his squadron except himself had experienced some degree of the retinal dysfunctions associated with high acceleration. He noted that during the runs he had been subjected to from 4.5 to 6.5 G. He recalled specifically that in 1955 during a dive bombing run from 10 000 feet he found himself in a dive with excess power and finding that his altitude was decreasing and his air speed increasing too rapidly he pulled out of the dive abruptly. During the pullout he noted that his accelerometer reached 7 G and that he actually passed the wing man who had been flying ahead of him in column formation. He grounded the aircraft for structural check after this experience in which again he had had no blackout or recognized grayout.

Physical examination revealed a well developed well nourished young white man who appeared healthy. The radial pulses were strong and the carotids were forceful. The femoral pulses were present but weak and lagged behind the radials. The abdominal aortic pulse was diminished. Dorsalis pedis pulses were present but weak. The blood pressure was 140/69 mm Hg in the right arm and 140/60 mm Hg in the left arm in the supine position with simultaneous readings. The upper extremity flush point was 110. The blood pressure in the left leg was 130/90 mm Hg and in the right leg 120/100 mm Hg. The lower extremity flush point was 90. There were no visible or palpable collateral arteries. The heart was essentially normal in size on percussion. A grade III systolic harsh blowing murmur was heard best in the third left intercostal space near the sternum but was transmitted to the precordium neck and back and was easily heard down the spine. A grade II diastolic blowing murmur was heard best in the fourth left intercostal space. The electrocardiogram was within normal limits. Fluoroscopy revealed slight enlargement of the left ventricle. A double indentation of the esophagus was seen with barium swallow. A roentgenogram showed minimal notching of the ribs. Operation revealed a coarctation with a 4 mm opening.

### DISCUSSION

That the occurrence of resistance to the effects of acceleration and the presence of coarctation of the aorta in this patient is more than coincidental is strongly suggested by the observations of Wood<sup>4</sup> and his associates at the Mayo Aero Medical Laboratory. They described a patient with coarctation of the aorta who showed a remarkable resistance to the effects of positive acceleration when tested in the human centrifuge.

The physics and experimental physiology of the retinal and cerebral ischemia which produces blackout and unconsciousness have been clearly presented by Wood and associates<sup>1</sup> and will only be touched on here. In the interest of orientation, a simplified diagram (fig 1) is used to show the relationships between the heart, brain, and retinas and the effect of acceleration in causing blackout and unconsciousness.

Figure 1 Levels of blood at various accelerations sup-  
 sure at heart level.

fixed pres

In the diagram the heart is represented as a pump operating at a constant pressure during the initial period of acceleration. This postulate has been experimentally demonstrated in centrifuge studies.<sup>4</sup> Circulation to the head is shown as a column of blood with outflows at cerebral and retinal levels. The dimensions in the figure are derived from the assumption that the mean blood pressure at the level of the heart is 95 mm Hg, which is equivalent to 125 cm of blood. The retina is indicated above the level of the brain to represent the intraocular tension of some 20 mm Hg, or 26 cm of blood, which must be overcome by the perfusing pressure. It is obvious that under normal conditions the height of blood in the column is more than adequate to perfuse both the retinas and the brain.

With the onset of acceleration each cubic centimeter of blood in the column increases in weight in direct proportion to the acceleration applied. It has already been established that, with the onset of acceleration and for a definite interval thereafter, the supporting pressure at the base of the column, i. e., the blood pressure at heart level, is constant. Further under ordinary conditions there would appear to be no obstruction to the immediate fall of the column which would occur as the weight of the column (and therefore its pressure at heart level) rose above the normal supporting pressure in the aorta at heart level. The distance the top of the column falls from its normal position is directly proportional to  $G$  so long as the blood pressure at the heart level is constant. For increasing values of applied  $G$  forces, the column of blood falls proportionately from its initial level as indicated in the figure.

It becomes plain in the figure that blackout must (as it does) occur before unconsciousness when acceleration increases. It is also evident that the height of the column of blood at any value of  $G$  is a function of the blood pressure at the heart level, so that rising blood pressure at heart level proportionally raises the height of the column at any value of  $G$ . This relationship is the crux of the problem of resistance to blackout, whether induced by an anti- $G$  suit or by coarctation of the aorta.

In coarctation the protective mechanisms might be ascribed to the frequent presence of hypertension above the level of the coarctation, to an unusually early and active response of the compensatory mechanisms which take place in acceleration,<sup>5</sup> or to the obstruction placed in a major pathway of retreat for the falling blood column under the influence of acceleration (fig. 1). The mechanism in this case is speculative and even in a case of coarctation studied in the centrifuge the available data do not clearly indicate the precise protective mechanism.<sup>1</sup>

## SUMMARY

An aviator with coarctation of the aorta seen recently at this hospital had increased resistance to the blacking out effect of acceleration. We have been able to find only one other report in the literature of this feature of coarctation. It is postulated that this resistance might be ascribed to the hypertension which exists above the level of coarctation.

Every doctor has a set of fairly firm beliefs as to which illnesses are acceptable and which are not how much pain suffering fears and deprivations a patient should tolerate and when he has the right to ask for help or relief how much nuisance the patient is allowed to make of himself and to whom, etc etc. These beliefs are hardly ever stated explicitly but are nevertheless very strong. They compel the doctor to do his best to convert all his patients to accept his own standards and to be ill and to get well according to them.

# Anterior Pituitary Insufficiency and Diabetes Mellitus

CHARLES B MOORE Lieutenant MC USNR

**D**IABETES mellitus in the presence of hyperfunction of the anterior pituitary has been fairly frequently reported but I have been able to find in the literature only 14 authentic cases of the concurrence of diabetes mellitus and spontaneous anterior pituitary insufficiency. This article presents the fifteenth recorded case of such a combination.

Although the incidence of the combination is not known the reported cases indicate that the diagnosis is being made with increasing frequency because (1) more tests are available to assay endocrine function properly and (2) more physicians now recognize the symptoms produced by anterior pituitary insufficiency. Thus of the previously reported cases of this syndrome six<sup>1</sup> appeared prior to 1930 and eight<sup>2-7</sup> since then. Autopsies were performed on the 11 patients who died usually soon after onset of anterior pituitary insufficiency. Of the surviving three one is reportedly doing well<sup>8</sup> one is receiving maintenance therapy and reportedly not doing well<sup>9</sup> and one is reported to be living without replacement therapy<sup>10</sup>.

Early diagnosis is essential and should be considered in any diabetic patient who suddenly requires less insulin or in whom insulin sensitivity develops. With proper replacement therapy and cautious medical care the patient may be returned to some form of productive life.

## CASE REPORT

A 35 year old white woman was admitted to this hospital on 17 March 1952 because of diarrhea and drowsiness of five days duration and some recent vomiting.

In November 1937 following a severe emotional upset malaise polydipsia polyphagia and loss of weight developed. Shortly after this a diagnosis of diabetes mellitus was made. The diabetes was well regulated in a hospital on a daily dosage of 20 units of protamine

# CASE REPORTS—PITUITARY INSUFFICIENCY

731

zinc insulin and 8 units of regular insulin. This dosage controlled the diabetes for several years. The patient was admitted to the same hospital on 14 October 1940 with clinical manifestations of a urinary infection and moderately severe diabetic acidosis, both of which were successfully treated, and when the patient was discharged 11 days later the diabetes was well regulated on a daily dose of 30 units of protamine zinc insulin.

On 9 July 1941 the patient was admitted to the same hospital with diagnoses of controlled diabetes mellitus, pregnancy of 35 weeks' duration, and early toxemia of pregnancy. The blood pressure was 130/95 mm Hg. Mild edema of the ankles was present. Slight improvement followed care in the hospital and the patient was discharged two days later. She was readmitted because of increasing albuminuria and edema. On 25 July, because of diabetes mellitus and toxemia, a cesarean section was performed. Profuse bleeding occurred because the placenta was in the line of the incision. Despite a transfusion of 500 ml of whole blood during the operation the patient remained hypotensive for several days. Four days following cesarean section shock developed, the blood pressure remaining around 70/40 mm Hg for several hours. Response to intravenous infusion of dextrose and saline solutions was slow. The patient was discharged on 8 August, the diabetes was well regulated on 28 units of protamine zinc insulin daily.

During the next few years the patient began to note a gradual decrease in the amount of insulin required and increasing difficulty in maintaining stable control of the diabetes. By April 1944 the insulin requirement had decreased to 6 units of protamine zinc insulin daily and the patient ate freely except for mild carbohydrate restriction. Sometime during 1944 she also noted menstrual irregularity for the first time. Prior to this she had menstruated regularly since her pregnancy. Between 1944 and the spring of 1952 she had occasional scanty menstrual periods after which her menses ceased completely.

Following severe mumps in 1948 the patient's health gradually but continually became worse. During the next few years the insulin requirement remained about the same (4 to 6 units of protamine zinc insulin daily) (fig. 1). The patient had no further bouts of diabetic acidosis. Two weeks prior to admission to this hospital she had experienced a severe infection of the upper respiratory tract.

At the time of admission in April 1952 the diabetes required 5 units of protamine zinc insulin daily but the patient had taken none for the preceding five days allegedly because of the diarrhea. Physical examination upon admission revealed a thin, pale, dehydrated white woman appearing chronically ill. Her blood pressure was 106/80 mm Hg, pulse rate 74/min, respiration 18/min, and temperature 97°F. She weighed 93 pounds and was 5 feet 3 inches tall. Initial laboratory

tests revealed a blood sugar of 102 mg/100 ml glycosuria a leukocyte count of 3 900/ $\mu$ l and an erythrocyte count of 3 600 000/ $\mu$ l

Figure 1 Diagrammatic representation of insulin requirement of patient over a period of 15 years

The patient was given 10 units of protamine zinc insulin upon admission. The same evening she became extremely pale, cold, and nauseated. She complained of difficulty in breathing and of a heaviness substernally. A few moments later she vomited 500 ml of gastric contents and complained of profound weakness. She continued to be cold and dry. An electrocardiogram was reported as suggesting electrolyte imbalance. Serum chloride was 73 mEq/l. Blood sugar was 52 mg/100 ml. The patient responded only lightly to an intravenous infusion of dextrose in water and Darrow's solution hypodermically.

The next morning she became nauseated and within profound insulin shock suddenly developed. This was followed by two generalized convulsions. During the next few days she gradually responded to supportive treatment but continued to be nauseated and ate little. Gastric intubation was necessary to maintain nutrition and after hydration anemia became apparent and required many blood transfusions.

A few days later another hypoglycemic reaction followed injection of 15 units of regular insulin which was given just before intravenous infusion of 1 000 ml of a 5 per cent solution of dextrose. When the infusion was started the blood sugar was 292 mg/100 ml and four hours later it was 46 mg/100 ml. The diarrhea improved rapidly with symptomatic therapy.

Ten days after admission, physical and roentgenographic evidence of right middle and lower lobe pneumonia developed. The pneumonia rapidly resolved following treatment with penicillin and the patient was discharged on a dosage of 4 units of protamine zinc insulin daily, to be followed in the outpatient clinic. A roentgenogram of the chest at this time revealed only slight residual infiltration in the right middle lobe.

During the next few months the patient continued to have a poor appetite, lost 22 pounds, was weak and had periodic bouts of nausea and vomiting. Moderate anemia, demonstrated at this time, failed to respond to the usual antianemic measures. In addition to loss of pubic and axillary hair the patient complained of loss of libido, cold intolerance and amenorrhea. These complaints, coupled with insulin sensitivity, suggested a diagnosis of anterior pituitary insufficiency.

The basal metabolic rate was reported to be in the hypothyroid range, although the exact values are not available. An  $I^{131}$  tracer study revealed an uptake by the thyroid gland in 48 hours of 4.8 per cent of the administered dose. Following a dose of 20 units of thyroid stimulating hormone daily for three days  $I^{131}$  was again administered on the fourth day. The 48 hour uptake by the thyroid gland then was 12.7 per cent of the administered dose.

The patient was therefore readmitted to this hospital on 6 October 1952 with a diagnosis of anterior pituitary insufficiency and diabetes mellitus. Physical examination revealed an undernourished cachectic white woman whose temperature was 98.6°F, pulse rate, 86/min and blood pressure, 86/68 mm Hg. Generalized wasting of the muscular and subcutaneous tissue was apparent. The hair on the head was dry and sparse and the axillary and pubic hair was considerably decreased. There was thinning of the lateral part of the eyebrows. The left pupil was smaller than the right and reacted sluggishly to light and accommodation. The tongue was slick. The breasts were atrophied. The skin was dry and had lost its normal turgor. The serum chloride was 95.8 mEq/l, serum sodium 133 mEq/l, serum potassium 4.4 mEq/l, red blood cell count, 4,200,000/ $\mu$ l, hemoglobin 12.5 g/100 ml, hematocrit 38 ml/100 ml, leukocyte count 4,850/ $\mu$ l with 2 per cent band forms, 42 per cent segmented polymorphonuclear leukocytes, 46 per cent lymphocytes, 5 per cent monocytes and 5 per cent eosinophils. Serologic test for syphilis was negative. Results of urinalysis were normal. The fasting blood sugar on admission was 72 mg/100 ml, but it varied between 63 mg/100 ml and 350 mg/100 ml while the patient was in the hospital. On 9 October the urinary neutral 17 ketosteroids were 0.9 mg/24 hours. The patient was given 25 mg of corticotropin (ACTH) every six hours for three days, and on the third day the urinary 17 ketosteroids were 2.6 mg/24 hours. On the following day they were 2.6 mg/24 hours. Following administration of 25 mg of ACTH the total

Figure 3 Photomicrograph showing severe atrophy of zona fasciculata and zona reticularis of adrenal cortex ( $\times 100$ )

Figure 4 Photomicrograph showing pituitary replaced by fibrous tissue except for a few parenchymal cells in the center ( $\times 100$ )

pituitary appeared normal. The lobules of the breasts were small and widely separated by relatively acellular hyalinized connective tissue, which stained deeply with eosin. The endometrium of the uterus was thin and lined by low cuboidal cells. The glands showed little evidence of secretory activity. The thyroid follicles were small and lined by low cuboidal cells (fig. 5). The lumina of most contained pink staining colloid which varied from dark to light pink. The interstitial tissue was dense and a large portion was hyalinized. There was diffuse lymphocytic infiltration as well as lymph node formation within the stroma. Mitotic figures were frequently seen in the germinal centers of the lymphatic nodules. In the ovary the germinal epithelium was composed of the usual low cuboidal cells. In the dense stroma there were a very few growing follicles. Several graafian follicles were present. The pancreas appeared normal.

Figure 5 Photomicrograph of a section of the thyroid showing small follicles and dense hyalinized interstitial tissue ( $\times 100$ )

### DISCUSSION

In a recent review of the literature on the Houssey phenomenon, Harvey and de Klerk<sup>11</sup> summarized the 11 previously reported cases and added three of their own. As in patients with anterior pituitary insufficiency without diabetes mellitus, the clinical picture tends to vary from patient to patient, depending upon the target gland whose function is most greatly affected. The syndrome has occurred with equal frequency in males. In females the most common cause is pituitary necrosis. Other causes include anorexia nervosa, infections, and arteriosclerosis. In only a few cases had the diagnosis been made with

# Fatal Anaphylactic Reaction to Lidocaine

LESLIE M MORRISSET Lieutenant MC USNR

**A**NAPHYLACTIC reactions, although not new are a constant threat to any patient receiving a medicinal agent. Thousands of new drugs are being introduced each of which has the potential capability of sensitization and subsequent anaphylaxis. A reaction of this nature produces a medical emergency that is hardly equaled. In many cases the survival of the patient hinges on immediate recognition and vigorous treatment. There is little reason to conclude that the number of anaphylactic reactions will decrease. Therefore the physician and dentist must be prepared to treat these reactions and must know their early signs and symptoms.

The employment of lidocaine hydrochloride as a local anesthetic has been associated with few upward reactions. Most of those that have occurred were not fatal and no prior report can be found of any death or serious reaction attributed to lidocaine anaphylaxis.

## CASE REPORT

A 20 year-old man was given approximately 0.8 ml of 2 per cent Xylocaine (brand of lidocaine) with epinephrine 1:50,000 for preparation for an operative dental procedure. About 45 seconds after the injection he was asked because of his paleness if he felt faint but before he could answer he became unconscious. His breathing became irregular and he went into convulsions which were transient. At this point artificial respiration was started. The patient was deeply cyanotic and except for an occasional gasp appeared to be dead. A medical officer who happened to be in the building gave caffeine with sodium benzoate to the patient but no change occurred and he was pronounced dead.

On two other occasions during the preceding two weeks the patient had been given injections of Xylocaine with epinephrine from the same lot that was used on the day of his death. The previous injections did not produce toxic symptoms.

No topical anesthetic solution was used on any of the three occasions. Tincture of Merthiolate (brand of thimerosal) was used as an

From U S Naval Station San Diego Calif Dr Morris is now at 1418 Ticonderoga Dr  
El Cajo Calif

antiseptic solution but no premedication was employed. This patient had previously stated on a printed questionnaire that he had had a reaction to sulfa drugs but had not indicated an allergy to any other drugs.

Autopsy Examination at autopsy revealed that the patient had been a normally developed well nourished young adult weighing an estimated 150 pounds. There was mild cyanosis of the nail beds and mucous membranes.

The heart weighed 275 grams. In the immediate subepicardial layer a few petechial hemorrhages were seen most frequently over the deepodent surfaces. Except for petechiae noted at infrequent intervals through sections the myocardium was normal. The cardiac chambers, valves and coronary arteries appeared normal. Each lung weighed 525 grams and had a rather boggy consistency. Several petechiae were noted on the pleural surfaces. The tracheobronchial tree was normal. The pulmonary vessels were clear. The spleen weighed 275 grams and the liver 1900 grams. Marked oozing of blood occurred from the rather distended hepatic venous channels. The gastro-intestinal tract and adrenal glands were normal in appearance. Cut sections of the kidneys revealed markedly congested cortical and medullary areas.

The cerebral convolutions were flattened due apparently to mild cerebral edema. Other than this flattening there was no indication of increased intracranial pressure. Closely spaced coronal sections throughout the cerebrum, the brain stem and the cerebellum revealed no specific abnormalities other than marked congestion of the meningeal and intracerebral vessels.

## DISCUSSION

Lidocaine is a tertiary amine with the chemical name of a diethylamino 2,6 acetoxydide hydrochloride. It may be used in infiltration, block, low caudal, topical, continuous caudal, peridural, and spinal (subarachnoid) anesthesia.<sup>1</sup> According to laboratory data<sup>2</sup> its advantages are that it (1) is the most stable anesthetic agent known and may be stored almost indefinitely or vigorously heated in the presence of strong alkali or acid without appreciably decreasing its potency, (2) has an unusually short latency period, (3) has wide clinical usefulness and is adaptable to all types of conduction anesthesia, (4) has rapid diffusion properties, (5) has a relatively low toxicity, and (6) produces profound anesthesia.

Although reported side reactions have not been fatal, the drug is capable of producing serious toxic reactions when used in excess of 500 mg. The total dose for an adult should not exceed 300 to 350 mg when using the 0.5 per cent ~~0.5 per cent~~ amount gives excellent results. A 1.5 ~~per cent~~ <sup>per cent</sup> This is

### LEAD POISONING IN CHILDREN

The diagnosis of lead poisoning should be considered in all cases in which children who have a pica for paint complain of constipation abdominal pain and vomiting. It should be given first consideration in cases in which children have an isolated convulsion that is not associated with fever or other physical signs. In such instances a simple test for porphyrinuria will indicate the possibility of lead poisoning. If porphyrin is present in the urine the blood should be searched for basophilic stippling and a roentgenogram of the long bones should be made in order to determine whether or not a lead line is present. An abnormal quantity of lead in the blood or urine will confirm the diagnosis.

# Delayed Obstruction After First Stage Repair of Omphalocele

JAMES B ANDERSON, *Major USAF (MC)*  
RICHARD P GOTCHEL, *Captain, USAF (MC)*

**O**MPHALOCELE is a rare lesion arising from an arrested reduction of the physiologic herniation of abdominal viscera which occurs and subsides during the sixth to the ninth week of gestation.<sup>1</sup> When the sac contains intestines alone, the incidence is one in 5,000 births, but when the sac also contains herniated liver, the incidence decreases to one in 10,000 births.<sup>2</sup> Between 1 October 1952 and 30 September 1955, there were three infants with omphalocele in 3,391 births at this hospital. This is considerably greater than the expected incidence.

## PURPOSE

This article reports the unusual complication of obstruction occurring three months after a first-stage repair, and contrasts the mortality of the two surgical approaches in management of large omphaloceles.

In a recent study of acute small bowel obstruction, omphalocele accounted for only 0.5 per cent of the cases in all age groups and for only 5 per cent of obstructions due to anomalies.<sup>3</sup> Although obstruction at the umbilical defect in association with omphalocele at birth has been reported,<sup>4</sup> late obstruction due to a narrowing defect following a first stage repair is not common.<sup>3, 4</sup> While it seems that such obstructions would be frequent, undoubtedly some of them are incomplete or subside unrecognized, consequently, attention is directed to the problem presented in case 1.

Despite one notable exception,<sup>5</sup> principles of management have not been sufficiently disseminated during the past five years. The need for wider and more current dissemination is illustrated by (a) the presentation at a recent surgical conference of a case of primary repair in an infant whose large herniation was forcibly reduced with fatal outcome, and (b) the management of an infant, born in October 1952 at this hospital, by difficult reduction

of a large omphalocele and primary abdominal repair which resulted promptly in respirator failure and death

### CASE REPORTS

**Case 1** A male infant was born on 16 October 1954 with a 10-cm omphalocele. Within four hours skin flaps had been mobilized under local infiltration and closed longitudinally over the intact sac. Under compression with plastic sponge and Ace bandage the mass became progressively more reducible.

At three months of age the child was readmitted because of vomiting and intermittent protrusions on each side of the upper aspect of his abdominal scar. He had refused his last feeding but distention was equivocal. A barium enema (fig 1) showed incomplete rotation but filling of the cecum to a point subjacent to the subcutaneous protrusions, moderate distention of small bowel, and a translucency of the protrusions suggestive of fluid only. Despite nasogastric suction

*Fig 1 (case 1) Barium enema roentgenogram made during second admission, prior to second stage repair*

findings of complete obstruction progressed. Surgical exploration disclosed edematous but viable cecum and terminal ileum irreducibly prolapsed through a 3 cm fascial defect. Proximally the ileum was distended (fig 2). Incisions relaxing the fascia permitted reduction and closure in layers after excision of excess tissue. Convalescence was uneventful and the child has remained well (fig 3).

rupture It is mandatory, therefore, to follow Dott's dictum that the infant should pass "from the womb to the operating table"

Treatment of large omphaloceles by reduction and primary closure in a series of 88 cases at the Boston Children's Hospital entailed a formidable mortality, namely, 25 per cent in infants with sacs measuring less than 7 cm, 70 per cent in newborns with sacs between 7 and 9 cm, and 85 per cent in those with sacs larger than 9 centimeters<sup>3</sup>

Staged management was originated and first reported by Gross and Blodgett<sup>4</sup> in 1940 Gross's modification, whereby the sac was not excised prior to covering with skin flaps, was reported in 1948 In contrast to the formidable mortality in primary closure, life expectancy in infants with large but otherwise viable omphaloceles treated by staged management at the Boston Children's Hospital was vastly improved Although obstruction arising from malrotation or from less frequent causes has occasionally necessitated subsequent operation, such theoretical complications as infection, cyst formation, sloughing of skin flaps, epidermal inclusions, and obstruction due to adhesions have failed to materialize<sup>5</sup> Malrotation is present in about one third and may give rise to obstruction requiring surgical relief at the time of the first-stage repair or subsequently<sup>3, 10</sup> Nearly two thirds of these infants have other anomalies which may be either inconsequential irregularities or serious cardiorespiratory, urogenital, or gastrointestinal defects

### SUMMARY AND CONCLUSIONS

Three newborn infants with large omphaloceles were treated at this hospital during the past three years, two by staged management with gratifying results and the other by difficult closure with a dismaying fatal outcome The unusual complication of delayed obstruction due to a narrowing fascial defect that required emergency second stage repair when the patient was three months old is reported

Large omphaloceles must be approached promptly by staged management To attempt primary closure by forcibly reducing herniated viscera into an inadequate compartment is to invite disaster, prompt relaxing incisions may avert this outcome when ever primary repair results in respiratory failure<sup>10</sup>

Covering the sac by skin flaps is a relatively simple procedure when done under local anesthesia, correction of other serious anomalies may require general anesthesia

Vomiting at any time postoperatively should be investigated forthwith to confirm or rule out intestinal obstruction

Enlargement of a small fascial defect at the time of the first stage procedure may preclude subsequent obstruction caused by progressive closure of the umbilical ring

## A MESSAGE FROM THE A M A

A medical news publication recently carried an item concerning a Department of Justice report of a record sum settlement in a malpractice case involving the United States. It was stated that the suit, in which an ex-servicewoman won a \$210,000 court judgment for disability resulting from continuous caudal anesthesia administered in a military hospital, was settled for \$175,000.

Medical professional liability is one of the most frequently discussed and most important subjects of interest to military and civilian physicians today. In December 1954, the Board of Trustees of the American Medical Association requested the A M A Law Department to plan and initiate a comprehensive study of medical professional liability. For the past two years, the Law Department has been conducting an exhaustive survey of this subject. It has collected facts, figures, and opinions on medical professional liability. This material has been studied and analyzed, and is now in the process of being made available to the medical profession.

In planning this study, it was decided that the following projects should be undertaken: (1) an analysis of state insurance laws and regulations, (2) a review of state statutes of limitation, (3) an analysis of reported cases, (4) an analysis of professional liability claims involving physicians in Government service, (5) a survey and analysis of pertinent state legislation, (6) a survey of state medical societies, (7) a survey of national medical societies, and (8) a sample survey of 5 per cent of the physician members of the A M A.

In addition to these projects, various topics were selected for articles to be included in a special series on the subject of professional liability. The topics to be covered are: (1) The History of Professional Liability Claims in the United States, (2) "Put It in Writing, Doctor", (3) Medical Legal Hazards: Anesthesia, (4) Physicians Expressing Opinions as to Form Treatment, (5) The Res Ipsa Loquitur Case, (6) The Rule of Respondat Superior, (7) Hazardous Therapy, (8) New Concepts in Professional Liability Suits, (9) Professional Liability Claims.

From the Council on National Defense of the American Medical Association. The views and opinions expressed are not necessarily those of the Department of Defense.  
—Editor

Pravention, (10) Profassional Liability Insurance Coverage (11) Profassional Liability Claims in England, and (12) The Law of Professional Liability

Professional liability claims involving military or federally employed physicians are usually instituted pursuant to the provisions of the Federal Tort Claims Act. Military personnel are precluded from recovery from the United States for malpractice under this law. However they may proceed against the physician and a judgment if rendered, would be against him personally. Military dependents usually proceed against the United States under the Federal Tort Claims Act in military malpractice cases.

Generally speaking, the legal principles governing medical professional liability of civilian practitioners are equally applicable to military and federally employed physicians with only minor exceptions. The military physician is personally responsible for negligence that results in injury to his patient in the same manner and to the same extent as if he were in private practice with one exception. If the injured person elects to proceed against the United States under the Federal Tort Claims Act and recovers a judgment against the United States the physician is relieved from pecuniary liability.

It is to be noted that under this Act there is no monetary limitation in the amount obtainable in a malpractice suit against the United States. However since administrative settlement of these claims is limited by the terms of the Act to amounts not in excess of \$1 000, it is readily apparent that few administrative settlements are made for personal injury alleged to have resulted from malpractice.

Since Government physicians whether they be in the military service or otherwise, are salaried personnel, no question generally arises as to the legal principles of the rule of *respondet superior* (let the master answer). Accordingly the Government is responsible for the negligent acts of its employees that are committed during the course of their employment. As a result and because of the guarantee of solvency and the relative ease of collectibility of a judgment against the Government malpractice suits are usually brought either against the Government alone or against the Government as a codefendant with the allegedly negligent physician employee.

Instances of suits against Government employees alone under the Federal Tort Claims Act have been and it would seem should continue to be relatively rare. As to further protection the physician employee may request and the Department of Justice will authorize the U S Attorney of Jurisdiction to assume the

defense of the employee, where to do so would best serve the interest of the United States

Beginning with the 2 February 1957 issue, selected articles on medical professional liability have been appearing in the *Journal of the American Medical Association*. Those articles will be reprinted in booklet form and will be available on request from the American Medical Association

## DISTINGUISHED VISITORS TOUR ARMY HOSPITAL IN GERMANY

During a 20-day field demonstration the U S Army 46th Surgical Hospital at Landstuhl Germany received visitors from all over Europe. Among them were NATO team member General Raffaele Squillacioti who is the Italian Surgeon General, USAREUR Medical Surgical Conference, and Army nurses attending a workshop here.

*General Squillacioti examining the new polaroid roentgenogram processing unit.*

General Squillacioti's tour of the mobile Seventh Army unit was representative of the reception accorded all the inspectors. Accompanied by his interpreter Major Antonio Mazzarella, the Surgeon General was briefed by Captain Bryan T. Lowe, hospital commander. Captain Lowe underscored the unit's mobility by stating, "Within two hours the 46th can be set up and ready to admit patients." He explained that its mission is to receive and care for nontransportable casualties.

At the request of General Squillacioti a résumé of the hospital's record followed which emphasized its efficient performance in Korea as the 351st Surgical Hospital

The Italian visitor began his inspection in the preoperative ward, where he observed admission procedures. He then proceeded to surgery, and described a display of surgical instruments as "among the finest I've seen." He contrasted the adjustable operating table with the fixed type used by the Italian Army.

In the X-ray Division a polaroid filming and processing unit, one of the first employed by a field outfit, was demonstrated. This new technic requires only 1 minute and produces a positive rather than a negative roentgenogram. The routine method used for detailed work, requires 10 minutes and yields a negative.

Viewing the nonmedical sections General Squillacioti registered approval and amusement at the "Man from Mars" rubber decontamination uniforms worn by chemical, bacteriologic, and radiologic teams.

---

#### HOW TO HOLD YOUR AUDIENCE

In a scientific meeting, like it or not, people will not listen to you unless you can catch and hold their interest. For this reason the presentation of a scientific paper is in some respects a show, and details of showmanship must be exploited. The nourishing of a stream of interest in an audience requires the use of "props"—usually lantern slides, occasionally models or exhibits—in which must be combined the unexpected, the pleasing, and the familiar with a slight variation. In this material, color, composition, and lighting (or ease of viewing) are of first importance.

—ROBERT P. BARDEN, M.D.

## ADMIRAL HOGAN RECEIVES GEORGETOWN UNIVERSITY AWARD

Rear Admiral Bartholomew W. Hogan, Surgeon General of the U. S. Navy, received the Georgetown University Vicennial Medal in recognition of many years of faithful and distinguished service at ceremonies held during the Founder's Day Convocation on 25 March 1957.

*Front and back of Georgetown University Vicennial Medal awarded to Admiral Hogan.*

The Georgetown University Vicennial Medal was struck as a symbol of gratitude and respect to the men who have devoted twenty or more years to Georgetown in her advancement in education. Admiral Hogan has been Associate Professor of Psychiatry at the University Medical School since 1936.

## OFFICERS CERTIFIED BY SPECIALTY BOARDS

### Supplementary Listing

According to information from the Offices of the Surgeons General of the military medical services, the following regular Medical, Dental, and Veterinary Corps officers have been certified by the boards indicated since the listings published in previous issues of this *Journal*

#### American Board of Orthopaedic Surgery

Harry B. Elsberg, Capt. USN

#### American Board of Internal Medicine

Nicholas G. Battiglietti, Maj. USA

Ray F. Fitch, Capt. USAF

Stephen J. Berke, Lt. Col. USA

Donald L. Howie, Lt. Col. USA

#### American Board of Pathology

Joseph F. Metzger, Maj. USA

John P. Ray, Jr., Capt. USA

#### American Board of Ophthalmology

Kenneth Somers, Col. USA

#### American Board of Surgery

Strother B. Marshall, Capt. USAF

William C. Turville, Comdr. USN

James E. McClenathan, Lt. Comdr. USN

Edward H. Vogel, Jr., Lt. Col. USA

William C. Rountree, Maj. USAF

#### American Board of Preventive Medicine

##### Public Health

Herschel E. Griffin, Lt. Col. USA

#### Board of Thoracic Surgery

(A Subsidiary Board of the American Board of Surgery)

Frank E. Hagman, Col. USA

Thomas H. Hewlett, Lt. Col. USA

#### American Board of Oral Pathology

Henry H. Scofield, Jr., Lt. Comdr. USN

#### American Board of Oral Surgery

Gerald H. Bonnette, Capt. USN

Edward A. Gargiulo, Comdr. USN

Donald E. Cooksey, Capt. USN

David Hazard, Lt. Col. USA

#### American Board of Pedodontics

Gordon H. Rovelstad, Comdr. USN

**Stop!**

The American Korean Foundation and the United States Army Medical Service have announced the discontinuation of their joint project of shipping to Korea medical books contributed by individual physicians medical schools hospitals and state and local medical societies Books should not be sent to the Sharpe General Depot in California as in the past for facilities no longer exist for packing and transshipping to Korea

The response of physicians and medical groups throughout the country to the appeal for books for Korean medical schools has been so generous that further contributions are not needed As a result of this program over 77 tons of medical texts references and periodicals valued at \$76 000 have been shipped to Korea for distribution to Korean medical schools

## A M A Military Medicine Section Meeting

A stimulating professional program will be presented at the annual meeting of the Section on Military Medicine of the American Medical Association's Scientific Assembly. The meeting will be held in the Coliseum located at Columbus Circle in New York City during the afternoons of 4, 5, and 6 June.

Speakers and discussants on the program include many prominent military and civilian physicians and scientists who will present a wide variety of timely and interesting topics.

Among the exhibits of the Military Medicine Section to be shown are

- Acute Respiratory Illness of Adenovirus (RI APC) Etiology in Military Populations
- Disease Free Laboratory Animals
- Newer Approaches to the Study of Liver Diseases
- Pediatric Diagnostic Clinic
- Psychiatry in the U. S. Navy's Operation Deep Freeze
- Clinical Diagnostic Studies Utilizing Radioactive Isotopes
- Present Day Method of Moving Poliomyelitis Patients
- Eye Protection Against Minuteman High Speed Missiles
- U. S. Air Force Occupational Health Program

The chairman of this section is Colonel Russel V. Lee, USAFR (MC) Inactive, and the secretary is Captain Cecil L. Andrews, MC, USN. The chairman's opening address will be on "The Military Surgeon—a Specialist."

Point credits for retirement may be earned by all eligible Reserve Medical Corps officers of the Army, Navy, and Air Force who register their attendance.

## Kimble Methodology Research Award for 1957

Nominations for the Sixth Kimble Methodology Research Award will be accepted until 1 June 1957 by the Conference of State and Provincial Public Health Laboratory Directors. This award established by the Kimble Glass Company, Toledo, Ohio, consists of \$1,000 and a silver plaque and will be presented at the annual meeting of the Conference in Cleveland, Ohio, in November 1957.

Candidates must be from the United States, its territories, or Canada.

To be considered for nomination, their work should be either (a) a fundamental contribution that serves as a baseline for development of diagnostic methods which fall within the province of the public health laboratory, or (b) the adaptation of a fundamental contribution to make it of use in a diagnostic laboratory.

Nominations may be made by authors, their associates, or others. A nomination should be accompanied by a statement justifying the recommendation, six summaries of the work, and six reprints. If reprints are not available, six summaries with bibliography will be accepted. Nominations may consist of a group of workers or one author. If the former, the cash award will be divided among the workers, but the plaque accompanying the cash award will become the property of the laboratory where the work was done.

Nominations should be sent to Howard L. Bodily, Ph.D., Chairman, Nominating Committee, Kimble Award, State Department of Public Health, Division of Laboratories, 2151 Berkeley Way, Berkeley 4, Calif.

## DEATHS

- BEXFIELD** Henry Nielsen Major, MSC USAR of San Luis Obispo Calif stationed at Detachment 2 9771 Technical Unit Dugway Utah attended the University of Illinois College of Pharmacy 1921 to 1923 commissioned a Second Lieutenant in the Army of the United States on 24 March 1943 died 20 December 1956 age 57 at Fitzsimons Army Hospital Denver Colo of lymphoblastic sarcoma of the lung
- BOUDREAU** Frederick Joseph, First Lieutenant DC USAR of Philadelphia Pa. stationed at 665th Medical Detachment Korea graduated in 1956 from Temple University School of Dentistry Philadelphia, Pa commissioned a First Lieutenant in the U S Army Reserve and ordered to active duty 14 June 1956 died 22 February 1957, age 25 in Korea, due to an aircraft accident
- CARPENTER** Sharon Opal First Lieutenant ANC USAR, of Washington D C. stationed at 33d Station Hospital USAREUR attended St Mary's College of Nursing, Calif and University of San Francisco Calif entered the military service 30 June 1943 and commissioned a Second Lieutenant in the U S Army Reserve 22 April 1953 died 22 February 1957 age 32 at Letterman Army Hospital San Francisco Calif of astrocytoma left cerebral hemisphere
- EDDY** Arnold Austin Captain MSC, USAR of Detroit Mich stationed at Fort Leonard Wood Mo entered military service 22 August 1938; commissioned a Second Lieutenant in the Army of the United States 9 June 1943 died 25 February 1957 age 38 at U S Army Hospital Fort Leonard Wood Mo of cirrhosis of the liver
- SHINABERGER** George Benjamin Second Lieutenant MSC USAR of Atlanta Ga stationed at Headquarters 3d USA Student Detachment Emory University Atlanta Ga attended Emory University 1953 to 1956, commissioned a Second Lieutenant in the U S Army Reserve and ordered to duty 3 September 1956, died 26 January 1957 age 24 at Atlanta Ga of multiple fractures and lacerations the result of an automobile accident
- SUMNER**, John Worthington Jr Lieutenant Colonel MC USA of Portland Conn stationed at Second General Hospital Germany graduated in 1941 from Columbia University College of Physicians and Surgeons New York N Y commissioned a First Lieutenant in the U S Medical Reserve Corps 3 June 1941 and Captain in the Regular Army 12 July 1946 died 24 February 1957 age 42 at the Second General Hospital Germany of myocardial infarction
- THOMAS** Howell Alexander Lieutenant Colonel DC USAR of Aransas Pass Tex stationed at Headquarters and Headquarters Detachment U S Army Hospital Fort Sill Okla graduated from Baylor University College of Dentistry in 1927 commissioned a First Lieutenant in the U S Army Reserve 13 July 1929 and ordered to active duty 9 July 1942 released from active duty 5 March 1945 and returned to active duty 12 February 1951 died 5 February 1957 age 54 at Brooke Army Hospital Fort Sam Houston Tex of a fulminating infection

## ROYAL AIR FORCE OFFICER COMMENDED FOR ACHIEVEMENTS IN AVIATION MEDICINE

In a ceremony at the Pentagon on 27 March 1957 Wing Commander E. Bruce Harvey Royal Air Force was presented with a letter of commendation from the Department of Defense by Dr Frank B. Berry, Assistant Secretary of Defense (Health and Medical).

*Dr. Frank B. Berry presenting letter of commendation to Wing Commander E. Bruce Harvey in the presence of the Surgeons General of the United States Army Major General Silas B. Hays, the United States Navy Rear Admiral Bartholomew W. Hogan, and the United States Air Force Major General Dan C. Ogle.*

The commendation signed by the Honorable Charles E. Wilson, Secretary of Defense, is reproduced on the opposite page.

May 1957)

ROYAL AIR FORCE OFFICER COMMENDED

763

THE SECRETARY OF DEFENSE

WASHINGTON

15 March 1957

Subject Commendation

To Wing Commander E Bruce Harvey Royal Air Force

With the full endorsement of the Surgeons General of the United States Army Navy and Air Force the Department of Defense commends you for your significant achievements in the field of aviation medicine during your tour of duty in Washington D C as Royal Air Force Liaison Officer to the United States and Canada This commendation refers particularly to your initiative and foresight in recognition of one of the major problems in aviation medicine and for your diligence and industry which led to the establishment of the Joint Committee on Aviation Pathology

This problem is the unexplained major aircraft accident with its resulting fatalities Excellent research work has been accomplished in both of our nations bearing on the causative factors involved In your country the brilliant work of Armstrong, Fryer, Stewart and Whittingham has contributed notably to an understanding of the Comet accidents in 1954 Stimulated by these investigations you displayed vision and resourcefulness in arousing the military medical services of the Department of Defense, and of the Royal Air Force the Royal Navy and the Royal Canadian Air Force to the desirability of uniting their efforts in a combined and comprehensive study of the human component in aircraft accidents through a Joint Committee on Aviation Pathology This Committee promises to be a cogent force in the development of tri partite action for the prompt collection and dissemination of pertinent clinical physiologic pathologic and experimental information to eliminate duplication of effort in our countries and hasten the progress of aeromedical research

By your superior devotion to duty keen professional judgment and diplomatic skill you have contributed immeasurably to the progress of aviation medicine and flight safety At the same time you have enhanced the bonds of friendship among the United Kingdom Canada, and the United States and coordinated a mutually beneficial approach to the solution of the causative factors of major aircraft accidents

A copy of this letter has been forwarded to your superior officer with the request that it be made a part of your official record

*C E Wilson*

## CORRESPONDENCE

*To the Editor*—I read the article on the "Treatment of Paraphimosis" in the March 1957 *Journal* and was quite interested. I recently served in Korea and was called upon to treat several patients with paraphimosis. I never encountered as severe a case as described in the article but did have two with acute paraphimosis. Although they were devoid of infection or necrosis, manual reduction was not possible and both patients were considered for surgical intervention by a dorsal slit. Before resorting to surgery, which would have been impractical at night at dispensary level, a half cc of hyaluronidase was injected into the edematous foreskin and massaged gently. Within five minutes the foreskin was easily reduced manually. This is not a large series but in the uncomplicated case of paraphimosis it is certainly worth a try, especially at the dispensary level. I hope this might be of interest to other dispensary medical officers.

DAVID K. GINSBERG, Captain MC USA  
U. S. Army Dispensary  
Indiantown Gap Military Reservation, Pa.

---

### **Second European Congress of Aviation Medicine to be Held in September**

The Second European Congress of Aviation Medicine will be held at Saltsjöbaden in the vicinity of Stockholm, Sweden, from 16 to 19 September 1957.

The main topics scheduled for discussion during the meeting are:

Gravitational Stress

Standardization of Tolerance Tests in Human Centrifuges

Trends in Engineering Psychology and Psychophysiology in Aviation Medicine

Decompression Sickness and Explosive Decompression

The president of the Congress is Prof. E. Hohwü Christensen, while the Chairman of the Executive Committee is Dr. Arne Frykholm. For full information in regard to the program and arrangements, address Dr. Olle Hook, Secretary General, Flygväpnet, Stockholm 80, Sweden.

## Reviews of Recent Books

THE PHYSICIAN WRITER'S BOOK *Tricks of the Trade of Medical Writing*, by Richard M. Hewitt A. M. M. D. 415 pages; illustrated W. B. Saunders Co., Philadelphia, Pa., 1957

Doctor Hewitt, onetime assistant editor of the *Journal of the American Medical Association* and in recent years senior consultant, Publications Section, the Mayo Clinic, has written a very practical guide to medical writing graphically and lucidly indicating the way to plan develop construct and finally finish a contribution to the medical literature. For many years now the profession has been in need of such a guide to medical writing.

The author with his mature outlook, thoroughly understands the problems confronting the busy physician who wishes to publish his observations. He indicates the many pitfalls to avoid and adequately demonstrates by example how this can be accomplished.

The author shows how to avoid "medicalese," "verbal arithmetical muddles" and the use of unauthorized abbreviations emphasizing the value of clarity, brevity, and good taste in the medical manuscript. He brings out by example the value of illustrations, the proper use of tables and even how to properly construct a sentence and build a paragraph. There is a valuable and interesting appendix which serves to elaborate on the textual material. The cross referenced index makes it easier for the reader to locate his precise point of interest.

This volume is of inestimable value to all physician writers, irrespective of their experience level.

—PAUL V. DAVIS Col USAF (MC)

FUNDAMENTALS OF CLINICAL FLUOROSCOPY With Essentials of Roentgen Interpretation by Charles B. Storck M. D. 2nd Edition 305 pages illustrated Grune & Stratton Inc. New York N. Y. 1957 Price \$8.75

The second edition of this popular text has been expanded to include new sections on neoplastic disease of the pancreas of the stomach, congenital heart disease, small bowel examination, intestinal obstruction and fluoroscopy of the gallbladder. Its aim is to give the student an intelligent meaningful approach to the study of application of diagnostic fluoroscopy. It is easy to read. The text is chosen photographs and diagrams are accompanied by questions consisting of specific questions and answers to test the student's features of diagnosis. Although the title suggests it is not a

clinical fluoroscopy as compared to radiographic examination the author stresses the importance of knowledge and skill in radiographic interpretation as a prerequisite to clinical fluoroscopy This requirement is effectively met by a well integrated presentation of the basic anatomy of both normal and abnormal radiographic features.

This text is highly recommended and merits the attention of those in the field of diagnostic roentgenology and is almost indispensable to beginners in the field of clinical fluoroscopy

—DELL F DULLUM Col MC USA

**OCCUPATIONAL THERAPY Principles and Practice** by William Rush Dunton Jr M D and Sidney Licht M D 2d edition 373 pages illustrated Charles C Thomas Publisher Springfield Ill 1957 Price \$8

For the physician who seeks a comprehensive orientation on occupational therapy this book is valuable This completely revised edition contains 16 chapters including new chapters on occupational therapy in pediatrics geriatrics remedial games and music in hospitals Each chapter was contributed by a different expert except that Dr Dunton and Dr Licht in addition to serving as editors served as author or coauthor on several chapters Particularly interesting are the chapters on cerebral palsy by Dr Winthrop M Phelps and on heart disease by Dr Paul D White

Orthopedic surgeons and physicians engaged in medical rehabilitation will find highly useful the chapters on kinetic occupational therapy and on the upper extremity amputee In the latter the dynamic approach of Rusk is reflected

This book is sturdily bound and attractively printed It is a must for the library of all who would join in the theme that the physician's duty is not fulfilled until the patient is restored to his fullest mental and physical capacity Occupational therapy as described in this volume can make a major contribution in attaining this important goal

—BENJAMIN A STRICKLAND JR Col USAF (MC)

**BORDERLANDS OF THE NORMAL AND EARLY PATHOLOGIC IN SKELETAL ROENTGENOLOGY** by Prof Dr Alban Köhl 10th edition completely revised with reference to illustrations and to text by Dozent Dr E A Zimmer Bern/Fribourg English translation (from the 10th German edition) arranged and edited by James T Case M D D M R E (Cambridge) 723 pages 1300 illustrations Gune & Stratton Inc N w York N Y 1956 Price \$24 50

This latest edition of a standard and excellent reference work deals as the title indicates with the borderlands of the normal in skeletal roentgenology The text is concerned primarily with what might be called the minutiae of skeletal anatomy The common as well as the rare deviations from normal that can be so troublesome to the radiologist are discussed concisely and authoritatively

This is not a book to be picked up and read from cover to cover. The subject material is much too encyclopedic in nature to be taken in one massive dose. It is, however, a valuable and authoritative reference book that one can turn to frequently to settle a moot point. For this reason it can be vastly important in medicolegal situations.

The second edition of this work, published in 1935, has been regarded by many older radiologists as an essential source of important information. The tenth edition is greatly expanded and benefits from the experience of hundreds of observers and writers listed in the voluminous bibliography.

The roentgenograms have been reproduced in the positive and are, for the most part, of excellent quality. They were carefully trimmed before reproduction and reveal only pertinent points of interest. There are also many photographs, diagrams, and line drawings of good quality. The index is adequate and the paper and binding are excellent.

The book is recommended to all radiologists and orthopedic surgeons.  
—ELMER A. LODIELL, Col. MC USA

**ADVANCES IN PEDIATRICS** Volume IX, 1957, edited by S. Z. Levine, 336 pages, illustrated. The Year Book Publishers, Inc., Chicago, Ill., 1957. Price \$9.

The current edition represents an improvement in this already excellent series. Among the subjects covered in this volume are post-maturity, the gamma globulins, thyroid disorders, familial dysautonomia, the coagulation disorders, and celiac disease.

Especially refreshing was the excellent summary of the effectiveness of fluoridation in the prevention of dental caries. The excellent summary of the various studies which have been carried out, presented here by Schlesinger and Ast, leaves little room for doubt as to the value of this measure. The excellent statistical approach provides the pediatrician with invaluable data for reassurance to parents and civic health groups. It is not possible in this review to mention all of the articles, but all provide new and interesting observations with excellent summations. —DANIEL STOWENS, Maj. MC USA

**THE YEAR BOOK OF GENERAL SURGERY** (1956-1957 Year Book Series), edited by Everts A. Graham, A. B. M. D., with a section on Anesthesia, edited by Stuart C. Cullen, M. D., 647 pages, illustrated. The Year Book Publishers, Inc., Chicago, Ill., 1956. Price \$6.75.

This latest annual volume in the series of surgical year books is as before composed of abstracts of representative articles from the surgical journals published during the past year. The book is divided into sections and articles in the various fields are grouped together. Articles are indexed by author and by subject material.

The abstracts are clear, well-written, and are representative of the general trends to be found in the voluminous literature. The

editorial comments underline important or controversial points. The diagrams are well drawn and labeled.

This volume ranks with its predecessors as an excellent reference for the recent surgical literature. It should, however, be used only as a reference for a more thorough study of the original articles.

In addition by selection and grouping of the articles the editor emphasizes recent trends in surgical thought and practice.

—PHILIP D. CRONMILLER, Comdr MC, USN

**ATLAS OF TUMORS OF THE NERVOUS SYSTEM** by H. M. Zimmerman M.D. and Martin G. Netsky M.D. and Leo M. Davidoff M.D. 191 pages 277 illustrations 233 in color 4 tables Lea & Febiger Philadelphia Pa 1956 Price \$25

This long-awaited Atlas presents for the first time a color treatise on tumors of the nervous system. The inadequacy with which black and white photographs depict gross and microscopic pathology is well known. The 233 color illustrations in this volume must represent the largest color collection on pathology in print.

The authors, two neuropathologists and a neurosurgeon, are well qualified to collect and present the material. The student and teacher in the fields of neurology and neuropathology have long been familiar with the various papers of Zimmerman and Netsky and the papers and books of Davidoff on the central nervous system are well known.

As with any color printing there are a few plates that do not appear to be "true" color. However, the majority of the plates are faithful reproductions.

The clinical and pathologic features of the various tumors are succinctly reviewed. An extensive bibliography covering the major works on each tumor is presented in the appendix.

This atlas will be useful to the student and teacher in the field of clinical neurology, neurosurgery and neuropathology. It will be an excellent guide for the candidate reviewing for American Board examinations. —ROBERT L. WILLIAMS Maj USAF (MC)

**CLINICAL PATHOLOGY: Application and Interpretation** by Benjamin B. Bell M.D. Ph.D. 2d edition 488 pages illustrated W.B. Saunders Co Philadelphia Pa 1956 Price \$8.50

Clinical pathology is truly the fusion of the laboratory and the bedside. A textbook on clinical pathology as written by the internist provides the medical student and physician guidance in the interpretation of the laboratory report. This book attempts to cover the entire range of clinical pathology from infectious diseases through the diseases of the various organs. Chapters are also included on clinical laboratory studies in surgery and in obstetrics.

The author's objectives are commendable and his introductory considerations are admirable. In essence he reaffirms the place of the physician in the care of the patient and advocates the use of the laboratory wisely, judiciously, and properly.

This book will serve as a compendium identifying the large variety of procedures and giving elementary interpretation. It will demonstrate that the clinical pathologist needs to assist the internist in the selection and interpretation of laboratory tests for the clinical patient.

—ABRAHAM BENENSON Lt Col MC, USA

**MANUAL OF ANESTHESIOLOGY** For Residents and Medical Students by Herman Schwartz M D, S H Ngai M D and E M Papper M D. American Lecture Series, Publication No 298, A Monograph in The Bannerstone Division of American Lectures in Anesthesiology, edited by John Adnani M D. 170 pages illustrated. Charles C Thomas, Publisher Springfield, Ill, 1957. Price \$4.25.

This 170 page manual is written for the medical student and resident in anesthesiology. It has achieved its avowed purpose by simple and concise wording. Nurse anesthetists should also find it useful.

The chapters on the physiology of respiration and circulation are particularly outstanding because of their clarity, simplicity, and excellent illustrations. The anatomy of the upper respiratory tract is well demonstrated. The chapter on physics as related to anesthesiology is useful in reviewing for board examinations. The beginner will find enough information in this chapter to understand the primary problems in medical physics.

The chapters devoted to clinical techniques are short and informative, while one of the longer chapters is devoted to pediatric anesthesia. This manual summarizes information needed by medical students for their course in anesthesiology. The nurse anesthetist student should find it useful as a text of basic information. The physician should find it an excellent book to familiarize himself with the entire problem of administering anesthetics.

The physician reviewing for examinations might find these capsules of information a stimulus to further reading.

—ARTHUR B. TARROW Col. USAF (MC)

**THE RECURRENT LARYNGEAL NERVES IN THYROID SURGERY** by William H. Rustad, M D. 47 pages illustrated. Charles C Thomas, Publisher Springfield Ill. 1956. Price \$4.50.

This monograph is written in a clear, concise and easy to read fashion. The first portion of the book very effectively reviews the historical background and gives a brief but complete discussion of the functional anatomy of the larynx, the embryology and anatomy of the recurrent laryngeal nerves, and an excellent summary of the clinical considerations necessary in the surgery of this area. The second portion is concerned with 11 groups of excellent anatomic

illustrations accompanied by concise descriptive material portraying the marked variability of the anatomy as found on dissection of 125 cadavers

This book is certain to stimulate increasing caution even by the most seasoned thyroid surgeon. It will be most useful to the trainee and as a quick review prior to performing operations of the region

—OAKLEY K. PARK, Lt. Col. USAF (MC)

**AMINO ACID HANDBOOK.** Methods and Results of Protein Analysis by Richard J. Block Ph. D. with the co-operation of Kathryn H. Weiss. A. B. 386 pages illustrated. Charles C. Thomas Publisher, Springfield, Ill. 1956. Price \$10.50

Dr. Block's most recent monograph provides detailed procedures for the determination of amino acids present in virtually any material plus a wealth of information concerning the amino acid composition of a wide range of proteins, polypeptides, and foods. Consistent with the handbook objective of this volume, there are more than 66 pages of references to the literature on protein analyses. A similar magnitude of space is devoted to tabular presentations of the amino acid composition of animal, plant, enzyme, virus, and food proteins. Dr. Herman J. Almquist has contributed a chapter on methods pertinent to the study of protein and amino acid requirements of animals.

The section on methodology begins with a very ample consideration of the means by which the specimen is prepared for analysis, including methods for the determination of nitrogen, the removal of lipids, nucleic acids, carbohydrates, inorganic ions, and the hydrolysis of proteins. Thereafter, there is a presentation of procedures for the determination of amino acids by chemical and microbiological methods and by the use of paper and column chromatography. The chapters dealing with the employment of micro-organisms and column chromatography were written by Dr. Sidney Saperstein and Dr. William G. Gordon, respectively.

The protein chemist will welcome this volume as a most valuable compendium of tested information concerning methods and results of amino acid analyses. The latter data will also serve well the needs of the various specialists who may require a knowledge of the natural availability of particular amino acids.

—THADDEUS J. DOMANSKI, Col. USAF (MSC)

**CYTOLOGIC TECHNIQS.** For Office and Clinic by H. E. Nieburgs, M.D. 233 pages illustrated. Grune & Stratton, Inc., New York, N.Y. 1956. Price \$7.75

This small volume is packed with information and methods for cytologic examination. In the 14 years since the publication of Papanicolaou's monumental work on the diagnosis of cancer by vaginal smear, cytological examinations have found an ever increasing field of application in cancer detection and treatment. The author has

gathered and condensed from his own wide experience and from the literature the most useful and important technics of cytology. Instruments and methods of collecting specimens are described. In addition to staining technics and diagnostic criteria, other facets such as laboratory organization and the training of technicians are covered and elaborated on with excellent photographs, photomicrographs, charts and diagrams. All physicians can find this book a valuable reference on cytology.

—ROALD A. GRANT Capt MC USN

**PRE AND POST OPERATIVE CARE IN THE PEDIATRIC SURGICAL PATIENT** edited by William B. Kieseewetter M D 347 pages illustrated. The Year Book Publishers Inc. Chicago Ill. 1956 Price \$7

This compact volume on the pre and post-operative care of infants and children is an excellent manual for the pediatric surgeon. The text written in outline form, is adequate and concise. It contains some standard formulas for the treatment of dehydration, acidosis, and other electrolyte problems that are valuable to the practicing surgeon as well as to the student. There are times when the surgeon does not have a qualified pediatrician available, and the material in this book helps in a measure to supply that need. As stated in the foreword, the replacement of blood, the maintenance of electrolyte balance and skillful anesthesia have made possible the performance of extensive surgery in infancy and childhood. The preparation of the patient for operation and the principles of healing are dealt with in this work. Each chapter provides a helpful bibliography for more extensive reading on subjects mentioned in the text. This book is quite well adapted to the needs of trainees in general surgery.

—ROBERT L. RHEA, Jr Col MC USA

**ANESTHESIA FOR SURGERY OF THE HEART** by Kenneth K. Keown M D, F A C A American Lecture Series Publication No. 304, A Monograph in The Bannerstone Division of American Lectures in Anesthesiology edited by John Adrian M D 109 pages illustrated Charles C Thomas, Publisher Springfield Ill. 1956 Price \$3.75

This volume is a handbook summarizing the author's knowledge gained during 10 years of experience with anesthesia in cardiac surgery. The history of open thorax anesthesia is traced from the 16th century. A complete list of cardiac irregularities is classified and discussed as to cause, diagnosis, treatment and significance. The most common occurring complications during anesthesia are noted, and emphasis is placed on prevention. The anesthesiologist's role in postanesthetic management is emphasized.

Each cardiac defect for which operation is indicated is given a specific chapter. This includes the pathologic physiology, signs and symptoms, roentgenographic and electrocardiographic findings, and data found by cardiac catheterization. Criteria for selection of patients for operation are enumerated, with descriptions of preanesthetic medication.

for each type of procedure. The necessity for the cardiologist, surgeon and anesthesiologist to work as an integrated team is emphasized.

The table of contents is detailed and eliminates the need for an index. There are no pictures nor illustrations except those showing catheterization data. This book is well organized, clearly written, practical and basic. It contains a lot of worthwhile information for any anesthesiologist and is an excellent manual for teaching.

—ROBERT E. LAU, Lt Col, USAF (MC)

**LESIONS OF THE CERVICAL INTERVERTEBRAL DISC** by R. Glen Spurling, M.D. American Lecture Series Publication No. 301. A Monograph in The Bannisterstone Division of American Lectures in Surgery, edited by Michael E. DeBakey, M.D. and R. Glen Spurling, M.D. Neurosurgery Division, edited by Barnes Woodhall, M.D. 134 pages, illustrated. Charles C. Thomas, Publisher, Springfield, Ill. 1956. Price \$4.75.

This volume is another of the American Lecture Series Monographs consisting of 134 pages devoted to a concise, carefully written study of the anatomy, pathology, diagnosis and management of cervical disk disease. There is a selected bibliography which includes the classical contributions to the literature. The 41 illustrations are effective.

The chapter on anatomy is confined to the clarification of the structural features pertinent to the subject. The section on the origin and pathology of cervical disk lesions is the most interesting part of the book, and the new thinking and experimental work are reviewed in a clear, logical manner. The remainder of the book outlines the diagnosis, management and results of treatment, using case histories as effective illustrations. This latter portion of the book is a positive presentation of the author's methods and experience. Most of the views are those in common acceptance among neurosurgeons.

A portion of the discussion concerning the effects of midline disk herniation and posterior vertebral osteophytes should be required reading for all clinicians. It emphasizes the dire consequences of overlooking these amenable but often insidious lesions.

The author has succeeded in making the book appealing to all physicians who deal with this often misunderstood syndrome. The reviewer believes that this admirable monograph will become as popular and authoritative as the author's classical book, "Lesions of the Lumbar Intervertebral Disc."

—ARTHUR L. SCHULTZ, Capt, MC, USN

**PEDIATRIC CARDIOLOGY** by Alexandre S. Nadas, M.D. F.A.A.P. 587 pages, illustrated. W. B. Saunders Co., Philadelphia, Pa. 1957.

This excellent, well illustrated book is arranged in four parts for the convenience of the physician interested in a particular phase of pediatric cardiology. It is an outstanding presentation devoid of all

repetitive syndromes and obsolete teachings which have appeared in most texts during the last few generations. The congenital heart lesions are clarified and handled in a practical manner, identifying them by their anatomic and physiologic abnormalities.

The material presented is based on the author's experience during the past 10 years in the Children's Medical Center in Boston. The clinical and hemodynamic features as delineated are quite similar to those which have been observed in the Congenital Heart Clinic at Walter Reed Army Hospital, in a 6 year study of over 1200 patients.

The book expresses the teachings and experience of recognized authorities in other fields with whom the author has been associated. These include such teachers as Clement A. Smith, Dr. Edward B. D. Newhauser, Robert E. Gross, and Walter T. Goodale.

This book fills the requirement for a much needed handy text and reference book on the subject of pediatric cardiology.

—THOMAS W. MATTINGLY Col MC USA

**CLINICAL USE OF RADIOISOTOPES** by William H. Brereton M.D., Philip C. Johnson M.D., and Arthur J. Solar B.S. M.S. (Physics)  
436 pages illustrated W. B. Saunders Co., Philadelphia Pa., 1957  
Price \$11.50

This text written by the personnel of the Isotope Unit at the University of Michigan Hospital, is the result of almost 10 years of teaching experience in the field. It is directed toward the resident and practicing physician and fills a need for a basic textbook.

Most of the volume is devoted to the common uses of isotopes in today's clinical practice and each chapter includes a review of anatomy, physiology, and pathology, as well as the isotope's applications. Approximately one third of the book is devoted to the use of  $I^{131}$  in the diagnosis and treatment of thyroid problems since this is by far the most common use of isotopes today. Separate chapters discuss the use of radioactive phosphorus and gold. The use of chromium, cobalt, and iron in various diagnostic tests is particularly well described.

The only possible criticism of the book is its weakness in dosimetry which is not unusual in most of the American literature. The common instruments are discussed and their fundamental circuits are illustrated. An appendix lists the formal radioisotope training courses, but does not include the courses at Walter Reed Army Medical Center, Washington, D.C., and the National Naval Medical Center, Bethesda, Md. Courses have been conducted at these installations for a number of years for military medical officers.

This book should provide a valuable addition to the limited library that is now available to people in the isotope field.

—JAMES B. HARTGERING Lt Col MC USA

MEDICAL SCIENCES Volume I Series VII of Progress in Nuclear Energy  
 edited by J C Bugher J Coursaget and J F Loutt 165 pages  
 McGraw-Hill Book Co Inc New York N Y 1956 Price \$6

This is the Medical Science volume of a new series of eight books based primarily on the papers presented at the International Conference for the Peaceful Uses of Atomic Energy held at Geneva in August 1955. A companion volume (Series VI) on the Biological Sciences is scheduled for early release. These two volumes will highlight the several hundred papers presented in these fields and originally published by the United Nations in six volumes.

In this edition the editors have selected papers relating to the role of radioisotopes in medical diagnosis and therapy illustrating new as well as established techniques of the use of these tools both externally and internally. In addition the principles of radiation safety the development of the concept of "maximum permissible exposure" and some of the attendant administrative and legal problems are thoroughly covered. Finally G Failla has written an excellent chapter on tissue dose concepts in terms of the rad—the international unit of absorbed dose.

The selected papers include succinct reviews by leading authorities as well as heretofore unpublished techniques or special adaptations and are arranged in such a way as to present a concise and coherent picture of the present state of the art in the clinical applications of nuclear energy. Where appropriate the editors have added clarifying remarks or additions. The chapters on Diagnosis by Belcher and Weyneord and Radioactive Materials for Internal Therapy by J S Mitchell are of particular value.

For the physician who does not have access to or time to study the original volumes published by the United Nations the editors have compiled an authoritative concise and readable version.

—JAMES B HARTGERING Lt Col MC USA

COMPARATIVE ANATOMY OF THE EYE by Jack H Prince F B O A  
 F S M C F R M S F Z S (London) 418 pages illustrated  
 Charles C Thomas Publisher Springfield Ill 1956 Price \$8.50

It is interesting and refreshing to come across a book on an unusual and relatively little known phase of ophthalmology. The book is interesting to read or even just to scan and has been made especially interesting and instructive by a liberal use of tables drawings sketches and photographs.

The author confines his work for the most part to the vertebrates from fish to mammals except for a small chapter on the invertebrates. He has systematized his study on an anatomic basis comparing similar anatomic structures of representative animals in each major group including man.

The "practical" ophthalmologist will not find anything here that will help him to treat patients but the well read ophthalmologist will

find much of interest. The researcher and serious student of comparative ophthalmology will find this work a treasure. The book's value is enhanced by its comprehensive bibliography, glossary of animal names, rapid reference table and chapter on comparative ocular dissection.—*KARL D. MACMILLAN Col MC USA*

**PRACTICAL DIAGNOSIS AND TREATMENT OF LIVER DISEASE** by *Carroll Moton Leevy M D* Foreword by *Franklin M Hanger M D* Illustrations by *Felix Traugott* 336 pages 84 illustrations including 23 in full color Paul B Hoeber Inc Medical Book Department of Harper & Brothers New York N Y, 1957 Price \$8.50

The author describes a method for correlating the clinical, biochemical and histologic changes that occur in disorders of the liver so that the disease processes might be better understood and treated. This book is intended as a guide for the practicing physician. The conclusions drawn are based on results of research and experience in 1,000 consecutive cases hospitalized with various hepatic disorders.

The chapter on clinical diagnosis is excellently presented with case reports and with an explanation of each symptom of liver disease and the mechanism of its development. The various laboratory procedures and the differential diagnosis of jaundice are discussed in great detail. The author outlines those tests of function which can be most readily used by the busy clinician with a small laboratory.

There is an excellent bibliography at the end of each chapter and illustrations of the microscopic histopathology are scattered throughout the book. This is an excellent book for a student, the general practitioner and the internist.—*EDWARD P. McLARNEY Capt MC USN*

**ULTRAMICRO METHODS FOR CLINICAL LABORATORIES** by *Edwin M Knight Jr M D*, *Roderick P MacDonald Ph D* and *Jaen Ploompuu* 128 pages illustrated Grune & Stratton Inc New York N Y, 1957 Price \$4.75

There is no question but that the universal adoption of ultramicro methods in the clinical chemistry laboratory would result in the elimination of untold numbers of agonizing venipunctures.

Every laboratory director must consider the possibility of instituting ultramicro (microgram and microliter) methods especially if he is required to do blood chemistry in infants and children. This small volume will help him to make a decision and having made it help him in implementing it. The authors describe the apparatus in their own laboratory at Harper Hospital in Detroit, Mich. and their single procedure for each type of determination.

Explicit directions are given for a comprehensive battery of examinations. Well chosen references to the pertinent literature enable the reader to expand his comprehension at any desired point. The in "recipe book" tedium is relieved by short but pithy disc interpretations.

MEDICAL SCIENCES Volume I Series VII of Progress in Nuclear Energy

**MEDICAL DEPARTMENT UNITED STATES ARMY** *Surgery in World War II*  
*Orthopedic Surgery in the European Theater of Operations* 397 pages  
 illustrated Editor-in Chief, Colonel John Boyd Coates Jr MC Editor  
 for Orthopedic Surgery, Mather Cleveland M D Associate Editor,  
 Elizabeth W McFetridge M A Historical Unit Army Medical Service  
 Office of the Surgeon General Department of the Army Washington 25  
 D C 1956 For sale by the Superintendent of Documents U S Govern-  
 ment Printing Office Washington 25, D C Price \$4

This excellent history of orthopedic surgery in World War II is a compilation of reports and clinical studies furnished by surgeons in the European Theater and skillfully edited by the Senior Orthopedic Consultant Colonel Mather Cleveland. Operational errors as well as successes are clearly defined and statistically recorded. Military and civilian surgeons alike will find this book of great value and timely interest.

The 397 page volume consists of three parts: administrative practices, clinical policies, and management of orthopedic injuries. The illustrations and printing are of superior quality and the type is easily read. There are two valuable appendices: the first dealing with care of battle casualty directives and the second a proposed revision of the orthopedic section of the Manual of Therapy. This section alone is well worth the thoughtful attention of every military surgeon and should be required reading.

More than 70 per cent of the casualties who survived in both world wars had wounds involving the upper or lower extremities. Considering the total troop strength in the European Theater of Operations approximated  $3\frac{1}{2}$  million men, one may appreciate the magnitude of the task which confronted the 243 military orthopedic surgeons assigned to this theater. Tribute should be paid to the two Senior Orthopedic Consultants, Colonel Rex L. Diveley MC and Colonel Mather Cleveland MC, as well as the 16 Junior Consultants for the success of the planned program and the competent treatment of bone and joint casualties.

Unfortunately, practically none of the experiences of World War I regarding the management of these injuries were put to immediate use in World War II. Treatment then was largely by the trial and error method. Review of this material by military surgeons should accomplish a great deal toward the prevention of repetition of past mistakes. The principles of management apply whether the casualties are military or civilian, and this would be especially true in case of a nuclear attack. Specific instructions are clearly presented with emphasis upon the adequate debridement of wounds, delayed primary suture of compound fractures, immediate primary suture of wounds of the hand, and proper treatment of joint injuries. As the Editor has stressed, the <sup>1</sup> word in the treatment of war wounds has not been <sup>2</sup> ~~was~~ <sup>3</sup> ~~important~~ <sup>4</sup> ~~advances~~ <sup>5</sup> ~~so arduously~~ <sup>6</sup> ~~learned in~~ <sup>7</sup> ~~not be forgotten~~ —EARL W. BRANNON Lt Col MC

It should be noted also that these techniques are widely useful in experimental studies on small animals

—ROBERT L. CRISWOLD M.D. Ph.D.

THE GIST OF OBSTETRICS by H. B. Atlee M.D. F.R.C.S. (Ed & Can.)  
F.I.C.S. Illustrated by Gail Vaughan, M.D. C.M. (Dal) 327 pages  
illustrated Charles C Thomas Publisher Springfield Ill 1957  
Price \$6

This is a new book written by the head of the Department of Obstetrics and Gynecology at Dalhousie University Halifax N.S. Canada and is the outgrowth as he states in the foreword of mimeographed notes for his students. The author makes no claim of originality of subject matter but he can claim originality of presentation and style. He presents the subject as "we" their teachers were practicing it in Halifax. The style is homely, chatty, lucid, concise and interspersed with wit and humor—a rare ingredient of modern "tomes."

This book lives up to its title. Either *good* or *modern* could properly be inserted into the title before "Obstetrics." It is hoped that this valuable book will remain what it is and not deteriorate in succeeding editions into a mediocre or second rate textbook as has happened to some of its predecessors. It is well bound, very readable, typographically and adequately illustrated with uncluttered line drawings.

The book can be highly recommended for student use and is a valuable, quick, practical source of compact, easily available information for interns, residents and general practitioners.

—ROY E. CROWDER Capt. MC, USN

THE TREATMENT OF FRACTURES by Lorenz Bohler M.D. Volume II translated from the 13th German edition by Otto Russe M.D. and R. G. B. Björnson M.D. 5th edition in English. Pages 1073 1508. Chapters 49 to 74. 941 illustrations. Grune & Stratton Inc. New York N.Y. 1957. Price \$17.50.

This entire second volume is devoted exclusively to disabilities of the femur. The first 93 pages present a thorough discussion of traumatic dislocations and gunshot wounds of the hip. Nearly 200 pages present the problems involved in femoral neck and intertrochanteric fractures. This is quite thorough and clearly points out essentials for success and reasons for failure in the treatment of these troublesome fractures. Discussion of the various other fractures of the femoral shaft and condyles, including missile fractures, comprise the remainder of the text.

It is somewhat surprising to see in print repeated recommendations for the use of heat in treating patients in shock. The assurance that femoral neck nonunions unite readily merely by performing closed reduction and nailing without any freshening of the fracture site may arouse skepticism. One case of 22 years' duration was so treated and healed solidly. Union is claimed for 87 per cent of 100 cases by this method!

Excellent illustrations are profuse and are better co-ordinated with the text than in the first volume. —WALTER R. MILLER Capt. MC, USN

## Monthly Message

During the past several years this office has been greatly disturbed over the failure of some of our medical schools to realize and prepare for the demands of the future upon medicine. This was brought to my attention very sharply the other day when I learned that one of our leading medical schools, with entering classes now of only 60 to 65, was planning to move and reduce its classes to a still smaller figure. With our rapidly expanding population and the many new fields of medicine with added opportunities and needs for physicians, this seems incredible. Bills are introduced into the Congress annually, expressing these needs and providing for the establishment of a Federal medical school. These bills are gaining more and more support and unquestionably part of the reason for this is the failure on the part of some of our leading medical schools to attempt to meet the pressing needs. Our universities are already making such preparations in their academic departments, and in order to retard the otherwise inevitable march of "socialized or state medicine," our medical schools also must make similar preparations.

Several years ago the State of New York took over the Long Island Medical College and the Syracuse Medical School. At that time they planned that over a definite period of years the classes in these two schools would show a steady increase up to a determined level. This is a good example of what all of our medical schools should be considering. Instead of resisting every effort to increase their classes and planning rather to reduce them, they should inaugurate a definite plan—call it by whatever name one wishes—to increase gradually the size of their classes up to calculated levels. It is far cheaper to proceed along these lines than it is to build new medical schools, and Federal aid for established schools will be more productive in a shorter space of time than will the building of a Federal medical school or schools.

Let us in medicine look forward, not backward and accept our present responsibilities and the imminent responsibilities of the future.

## Foreword

The *United States Armed Forces Medical Journal* is the medium for disseminating information of administrative and professional interest to all medical personnel of the Department of Defense. The Assistant Secretary of Defense (Health and Medical) and the Surgeons General of the several service invite all medical officers, dental officers, Medical Service Corps officers, Nurse Corps officers, and officers of the Veterinary Corps of the Armed Forces, and the medical consultants of the Army, Navy, and Air Force to submit manuscripts for publication in this journal.

## WHO, ME TEACH?

SILAS B. HAYS, Major General MC USA

**W**HY is it that so many leaders in medicine have professional appointments in medical schools and teaching hospitals? Do they hold these appointments because they are especially competent or, conversely, have they developed competence because they are actively engaged in teaching?

I think the answer to both of these questions must be in the affirmative. It is a truism that the teacher learns more than the pupil, and nowhere is this more true than in the field of clinical medicine. The teacher must consult, read, and study if he is to keep ahead of his pupil. In the discussion of a disease entity or of an individual patient, he is subject to constant question and challenge.

The teaching of clinical medicine is not, and should not be, confined to medical schools and "teaching" hospitals. Every day, all over the world, doctors get together to study and discuss individual cases with a view of determining diagnoses and methods of treatment. While sometimes these discussions or consultations are between doctors of equal professional competence, more frequently they are between a "senior" man and a "junior" man. In the Army, with its general pattern of group practice, such consultations are particularly frequent. In fact this is one of the outstanding attractions of a military medical career.

Are we in the Army making the most of these opportunities to improve our knowledge and competence and thereby improve the quality of our patient care? The solution is not to be found in

---

General Hays is the Surgeon General, Department of the Army, having held this office since 1 June 1955.

pious statements of policy, nor in directives emanating from some headquarters. It lies in the development of a teaching atmosphere in all of our medical groups. If each of us develops the habit of teaching every day, we will automatically provide better medical care for each of our patients.

Paraphrasing Shakespeare's *Twelfth Night*. Some are born teachers, some acquire teaching ability, and some have the teaching role thrust upon them. The born teacher can't keep from teaching. In every discussion and consultation he imparts knowledge. I have frequently cited my personal experience with one of our outstanding surgeons, Leonard D. Heaton. In 1932 I reported to old Tripler General Hospital which then had a small staff and far less than 100 patients. It was definitely not a "teaching" hospital. I was Captain Heaton's assistant on surgery. With Captain Heaton, every case was a teaching case and I learned something from every patient we saw together. Perhaps also some of my questions stimulated him to further reading and study. I know that I profited from every hour. Twenty three years later I watched Major General Heaton in the operating room at Walter Reed Army Hospital. He was assisting a surgical resident on a case of polyposis of the colon. General Heaton was just as he was in 1932—explaining and teaching by the "conch and pupil" method. The resident was learning surgery by the best means that has been discovered.

What about those who are not "born teachers"? Teaching skills may be acquired by those willing to take advantage of opportunities. There are only two real requisites—a knowledge of the subject and a desire to teach. It is the rare individual who finds teaching difficult or embarrassing if he meets these two requirements. On the other hand, if one is uncertain of his knowledge he is naturally reluctant to assume the teaching role. Likewise if he is not motivated to teach he loses his opportunities slide. But the inescapable fact is that teaching itself forces deeper thought and stimulates more study. Teaching is not only an altruistic action to help the other fellow. It is also a means of self advancement—a most honorable means. The best way to acquire teaching skill is to teach. It is never too early or too late to start.

What can we do about this? As Surgeon General of the Army, I am interested in constantly improving the quality of our patient care. Aside from this—and the two are inseparable—I am also interested in improving the professional stature and over all competence of all Army doctors. The difficult part of this program is that what is everybody's responsibility is usually nobody's.

responsibility. On the other hand, the easy part of the program is that everyone can do something about it either on his own or as a participant in an organized effort. The individual doctor not only can develop the teaching attitude in himself but he can help evolve a teaching atmosphere in his organization. The service chief can encourage ward rounds, conferences, journal clubs, and many other activities which center around teaching. The commander can likewise do much. He can arrange symposiums and clinical pathologic conferences and encourage talks by the staff. He can encourage timid and reticent individuals to speak in open meetings. He can invite medical officers from other units and doctors from the civilian community to attend professional meetings. He can stimulate good relationships with the local medical society and arrange for participation in programs. Often, by precept a spark thrown off from a leader will set ablaze the fire smoldering in the mind of one whose capabilities have not yet been recognized. Because good teaching further improves good patient care and elevates the competency of doctors in the Army, I am determined to constantly strengthen our teaching capabilities and facilities. Each Army hospital must have its staff actively interested in teaching and learning.

My discussion has concerned doctors of medicine, but is not restricted to them. It embraces all members of the Army Medical Service—dentists, veterinarians, nurses, psychologists, chemists and all professional groups, administrative officials, civilian employees, and enlisted personnel. Learning is unaware of rank. We all gain knowledge from our "juniors," as well as our "seniors." Enlisted personnel constantly make valuable contributions to teaching and patient care.

This is a program in which nobody loses and everybody gains the patient, the teacher, the pupil, and the Army Medical Service. I urge all to teach.

# CLOSING OF ATRIAL SEPTAL DEFECTS WITH THE AID OF HYPOTHERMIA

DAVID E. THOMAS *Lieutenant Colonel MC USA*

**A**TRIAL SEPTAL defects which are possibly the most common of the isolated congenital anomalies of the heart, have been treated by a variety of closed operative techniques. Gross and associates<sup>1</sup> used a rubber "well" attached to the right atrium and, as a result of the low pressure in this chamber were able, working through a pool of blood, to leisurely close the atrial septal defect with sutures. Bailey and co-workers<sup>2</sup> used a method involving inversion of the atrial tip into the septal defect, blindly suturing it in this position. Søndergaard's<sup>3</sup> technic consisted of dissecting in the interatrial septum between superior and inferior vena cava and, with a finger in the auricle for guidance, passing a needle with suture about the defect. This suture was tied by the assistant; the operator's intracardiac finger checking on the closure obtained.

Of these methods, that of Gross seems most practical but all are deficient in that visualization is not possible. It is well known that atrial septal defects are often cribriform and it is not unusual to find a large defect with several small ones. Inadvertent failure to close all defects must occur in any method not done under visualization. In addition, detection and correction of associated anomalies such as pulmonary venous drainage into the right auricle is possible under visualization, and the coronary sinus may be protected from partial or complete occlusion by a suture.

Lewis and Taufic<sup>4</sup> reported the first successful case of interatrial surgery under direct vision during hypothermia in 1952. Since then numerous reports have appeared in the literature. Swan and his group<sup>5</sup> have been particularly prominent in this field and we are indebted to them for leadership and guidance at this hospital. It would seem obvious that if the operation can be performed with a mortality comparable to that of the closed technics, repair of interatrial septal defects by direct

---

*From Fitzsimons Army Hospital, Denver, Colo. Col. Thomas is now assigned to Valley Forge Army Hospital, Philadelphia, Pa.*

vision under hypothermia is the procedure of choice and will yield a higher percentage of successful closures. With this objective in mind, let us evaluate our results.

### METHOD

**This study** includes 18 operations from 1953 through 1956. Two of those were reoperations. Seventeen were performed with the aid of hypothermia and 1 with the bubble oxygenator described by Dollall and associates.<sup>6</sup> The technique of cooling and operation has been thoroughly described by Salzer, Lyter, and Pollock<sup>7</sup> and will not be repeated.

**Age at Operation.** Ages varied from 4 to 38 years. Ten patients were less than 10 years of age, 4 were 20 to 30, and the remaining 4 were 30 to 38 years of age.

**History.** In general, a history of retarded growth, dyspnea on exertion without cyanosis, and frequent respiratory infections was obtained. The lack of cyanosis is to be expected, because the shunt is from left to right. The severity of symptoms varied from asymptomatic, the lesion being discovered as the result of a prenatal examination, to very severe with marked limitation of activity.

**Physical Findings.** The patients were generally underdeveloped and underweight. The left anterior portion of the chest may be prominent and a thrill or shock is often felt in the pulmonic area. The heart is enlarged to percussion. A soft systolic murmur is heard along the left sternal border. The second heart sound is duplicated and loud, and a soft diastolic murmur may be present.

**Roentgenograms.** There was increased vascularity of the lung fields, enlargement of right auricle and ventricle, posterior displacement of the esophagus by the right auricle on barium swallow and, on fluoroscopy, increased pulsation of the pulmonary artery.

**Cardiac Evaluation.** Electrocardiograms often showed incomplete right bundle branch block and evidence of right ventricular hypertrophy. Cardiac catheterization revealed evidence of a left to right shunt at the atrial level with increased oxygenation of the blood. Mild to marked right ventricular and pulmonary artery hypertension was frequent. Pulmonic to systemic circulation ratios ranged to a high of 4 to 1.

### RESULTS

Table 1 lists the complications of the procedure in our series. There were 2 deaths in 18 procedures, a mortality rate of 11

per cent. Neither of these deaths were considered to be a result of hypothermia. One was due to bronchopneumonia on the third postoperative day. The other was first thought to be caused by pulmonary embolism the patient dying suddenly on the day she was to leave the hospital. This impression was not confirmed by autopsy, which showed no definite cause of death. Inasmuch as she exhibited ventricular fibrillation during the operation and developed auricular flutter which responded to digitalis and quinidine during the postoperative period it was believed that she probably died as a result of ventricular fibrillation.

TABLE I Complications

Ventricular fibrillation	4
Atelectasis	2
Pneumonitis	2
Bronchopneumonia	1
Bilateral common peroneal palsy	1
Incomplete closure	1

Incomplete closure was diagnosed in a 5 year old boy when he failed to improve following surgical intervention. Reoperation was successful.

Of the remaining complications the only one of importance was the bilateral common peroneal palsy. This unusual complication occurred in a 29 year-old man who required four electric shocks at 165 volts for 0.1 second to stop ventricular fibrillation during the operation. He had anomalous pulmonary venous drainage into the right auricle from the right lung. The ventral portion of the atrial defect was sutured to the right auricular wall on the right side of the anomalous pulmonary veins thereby shifting the venous return to the left auricle. In spite of the e problems circulation occlusion did not exceed 5 minutes which is well within the safe range. This patient is exhibiting a slow return of function but still requires foot-drop braces.

Anomalous right pulmonary venous drainage was diagnosed preoperatively in another patient as a result of catheterizing a right pulmonary vein during cardiac catheterization. This additional defect was remedied by the method previously described with good result. Artificial oxygenation with the bubble oxygenator was used during this series. No septum primum defects were encountered in this series.

The other reoperation was on a patient who had previously had a polyethylene button sutured over the defect under hypothermia.

at another hospital. At operation at this hospital, the button was found to be covered with endothelium, but one suture had pulled out. The button was resutured with good result.

Follow up evaluation is available on 13 patients. Eleven of them report weight gain, increased strength and vigor, and unlimited activity. One patient has residual symptoms from peroneal palsy and one, diagnosed preoperatively as having a psychogenic musculoskeletal disorder without true cardiovascular symptoms, reports no postoperative improvement.

### COMMENTS

Rapid advances in cardiac surgery during recent years have posed the problem of comparing various techniques and selecting the one best suited for correction of a specific anomaly. This small series of cases indicates that under direct vision with the aid of hypothermia, atrial septal defects can be closed successfully and completely with an acceptable mortality rate. The postoperative improvement of the patients is uniform and gratifying. The open heart method of repairing this defect is considered to be technically superior to any of the closed methods. Necessary intracardiac manipulations can be completed well within the eight minute safe period of vascular occlusion. In fact, the operations on these patients were all completed within five minutes, insofar as the intracardiac portion of the procedure was concerned. It is possible to repair the defect in three minutes in a straightforward case with a foramen ovale type of central defect. It has never been necessary to do so, but, should the time within the open heart approach eight minutes, the procedure could be temporarily interrupted, circulation and respiration be reestablished, and the heart be reentered after an adequate interval.

Air embolism has not been a problem, because the left heart is flooded with physiologic saline solution through the defect just prior to tying the last suture. The right auricle and ventricle are similarly flooded prior to clamping off the incision in the auricular wall. The coronary arteries are protected from air embolism by placing the clamp that occludes the aorta and pulmonary artery low enough to occlude the coronary ostia.

Ventricular fibrillation has been a problem, but not an insurmountable one in this series. For the past year, we have injected Novocain (brand of procaine hydrochloride) into the sinoauricular node area, as recommended by Riberi, Sideris, and Shumacker,<sup>4</sup> but a firm opinion of the value of this procedure has not been formed. Fibrillation has occurred after Novocain injection of the S A node area. Ventricular fibrillation is ignored

during the open heart portion of the procedure but massage is started as soon as the incision in the right atricular wall is clamped. Massage and electrical defibrillation have been successful in restoring normal rhythm. Intracardiac injections of dilute epinephrine and calcium chloride solution are occasionally used as auxiliary measures. We have not employed intracoronary infusions of potassium solutions to induce cardiac standstill.

### SUMMARY

Atrial septal defects have been treated by a variety of closed operative techniques. Direct visualization during operation permits (1) more complete closure of the defect, (2) detection and correction of associated anomalies such as pulmonary venous drainage into the right atrium and (3) protection of the coronary veins from partial or complete occlusion by a suture.

From 1953 through 1956 16 operations for closure of atrial septal defects were performed under hypothermia at this hospital. There were two postoperative deaths. One on the third postoperative day resulted from bronchopneumonia. The other at the time the patient was ready to leave the hospital probably was caused by ventricular fibrillation.

This small series of cases indicates that under direct vision with the aid of hypothermia, atrial septal defects can be closed successfully and completely with an acceptable mortality rate. The postoperative improvement of the patients was uniform and gratifying. The open heart method of repairing this defect is considered to be technically superior to any of the closed methods.

# USE OF ANORGANIC HETEROGENOUS BONE IN ORAL BONY DEFECTS

PHILIP J BOYNE, *Lieutenant Commander DC USN*

FRED L LOSEE *Captain, DC USN*

**T**HE organic fraction of bone may be removed by extraction with ethylenediamine, with a minimum of alteration in the structure and composition of the inorganic component<sup>1,2</sup> The resulting osseous product, consisting of a porous crystalline and noncrystalline lattice, has been termed "anorganic bone" and has served as a successful foundation for new bone growth in defects of the long bone of dogs<sup>3</sup>

This pilot study was undertaken to evaluate clinically the use of animal inorganic bone in patients undergoing selected oral surgical procedures It was thought that a clinical evaluation of the oral tissue response could be obtained by implanting anorganic cortical bovine bone particles into bony defects following relatively minor operative procedures

Boyne and Losee<sup>1-3</sup> found that the placing of anorganic bovine bone particles in surgically created bony defects of the mandible and maxilla of rhesus monkeys was followed by uneventful clinical healing with a complete absence of any evidence of a foreign body reaction Histologic specimens of the implanted defects demonstrated reactive bone formation surrounding the anorganic particles as early as 13 days postoperatively The anorganic particles were rapidly remodeled with new bone formation from the host tissue

It is believed that on the basis of this previous experimental work on the rhesus monkey, ethylenediamine extracted animal bone offers a new source of osseous tissue which could be applied to many oral surgical procedures as a substitute for fresh autogenous bone, banked homogenous bone, or various alloplastic materials

Such a substitute is particularly applicable to the military service where there is need of an inexpensive, readily avail

---

From Dental Service Naval Dispensary Department of the Navy Washington O C and Dental Division Naval Medical Research Institute National Naval Medical Center Bethesda Md

able source of osseous tissue for use in the treatment of traumatic injuries in the event of a national emergency.

The purpose of this study was not to compare anorganic animal bone implants with autogenous or homogenous bone transplants but merely to establish whether the implanting of anorganic bone particles into oral bony defects of man would be followed by the same clinical and roentgenographic pattern as that observed in the monkey following the filling of similar defects with the same material.

A total of 16 anorganic heterografts were placed in various types of bony defects. Three of these implants were placed in the bone cavities following the enucleation of radicular cysts, 6 were placed in periapical bony defects following endodontic therapy and periapical curettage, 3 were placed following enucleation of nasopalatine duct cysts and 6 were placed in the bone alveoli following tooth extraction. In all patients healing was uneventful. postoperative edema and ecchymosis were minimal and no untoward reactions were observed. In no case was there any clinical evidence of foreign body response by the oral tissues. In some patients immediate denture prostheses were inserted over the operated areas without discomfort to the patient and the tissues healed rapidly beneath the prosthetic appliances.

The length of the postoperative follow up period varied from 10 to 20 weeks. Roentgenograms taken 6 weeks postoperatively demonstrated a tendency toward uniformity of bone density between the grafted areas and the surrounding bone, the development of an apparently normal trabecular pattern was demonstrated in the latter part of the postoperative course.

Two representative cases are briefly reported to demonstrate the use of this material.

### CASE REPORTS

**Case 1** A 32 year-old man first reported to the dental clinic with the complaint of "pain and swelling of the upper jaw." A preoperative roentgenogram (fig. 1) disclosed a large radiolucent area in the edentulous right maxilla extending from the apex of the right cuspid tooth medially to join another radiolucent area in the midline of the maxilla. At operation these cystic areas in the maxilla were enucleated and anorganic bovine bone particles were implanted in the bony defects. The left lateral incisor and the right cuspid were removed. A partial denture was inserted over the area at the time of the operation. On microscopic examination the cystic areas proved to be a radicular and a nasopalatine duct cyst. Figure 2 is a roentgenogram taken one week postoperatively. A roentgenogram made six weeks postoperatively

*Figure 1 (case 1) Preoperative roentgenogram demonstrating large radiolucent area in edentulous right maxilla.*

*Figure 2 (case 1) Roentgenogram taken one week after enucleation of cysts and implantation of anorganic bone particles*

(fig. 3) revealed a tendency toward uniformity of density of the osseous tissues. None of the implanted bone particles had been extruded or exfoliated. Clinically, the edentulous ridge was firm and well healed.

Figure 3 (case 1). Appearance on roentgenogram six weeks postoperatively.

Figure 4 (case 2). Operative site showing bony defect following enucleation of cyst.

**Case 2.** A radicular cyst involving the left upper central and lateral incisor teeth of a 24 year old man was enucleated by periapical curettage. The bony defect remaining after the enucleation is shown in figure 4. It was possible to retain the involved teeth by endodontic therapy. Figure 5 shows the operative site following the placing of anorganic bovine bone particles in the bony defect. The mucoperiosteal tissues were closed over the implanted bone particles. Healing was uneventful.

*Figure 5 (case 2) Operative site after placing anorganic bone particles in the bony defect*

#### SUMMARY AND CONCLUSIONS

The organic portion of bovine bone was extracted with ethylenediamine. Particles of the remaining anorganic bovine bone were used as grafts in 18 bony defects created by relatively minor oral operative procedures. The bony defects in each case were slightly underfilled and a close adaptation of the mucoperiosteal flap was obtained. The absence of any inflammatory response clinically and the retention of the graft, without extrusion or exfoliation of the graft particles, were indicative of initial clinical host acceptance.

Limitations, both in the number of cases reported and in the length of the follow up periods, preclude the establishing at this time of any definite conclusions as to the ultimate fate of

#### SUMMARY AND CONCLUSIONS

The organic portion of bovine bone was extracted with ethylenediamine. Particles of the remaining anorganic bovine bone were used as grafts in 18 bony defects created by relatively minor oral operative procedures. The bony defects in each case were slightly underfilled and a close adaptation of the mucoperiosteal flap was obtained. The absence of any inflammatory response clinically and the retention of the graft, without extrusion or exfoliation of the graft particles, were indicative of initial clinical host acceptance.

Limitations, both in the number of cases reported and in the length of the follow up periods, preclude the establishing at this time of any definite conclusions as to the ultimate fate of

these implanted anorganic heterografts. The absence of any clinical evidence of foreign body reaction on the part of the host, however, and the character of the postoperative roentgenograms indicate a pattern of host acceptance similar to that found in animal experimentation (implantation of anorganic bone in the long bone of dogs and in oral bony defects of monkeys).

Anorganic bone is easily manipulated. It may be kept at room temperature and need not be stored under sterile conditions or in an antibiotic solution, because it is autoclaved just before its use in an operation. This material appears to be adaptable to the surgical techniques used for the insertion of autogenous or banked homogenous bone particles in bony cystic defects of the oral cavity (*e g* freeze dried homogenous bone<sup>7</sup>).

It is believed that further studies on the clinical and roentgenographic long term status of anorganic bone grafts will indicate a definite application of this material to many oral surgical procedures.

# RELATION OF PLASMA PEPSINOGEN LEVELS TO ETHNIC ORIGINS

## Implications in Duodenal Ulcer

SYDNEY H. CROOG, *First Lieutenant MSC USAR*

**R**ECENT research has indicated that 87 per cent of patients with duodenal ulcer have higher blood plasma pepsinogen concentrations than do normal subjects.<sup>1</sup> In addition, it has been suggested that under appropriate circumstances, persons with comparatively high levels of serum pepsinogen are more likely than others to develop duodenal ulcer.<sup>2</sup> Although further study is necessary to establish and clarify the exact nature of this phenomenon, the elevation of plasma pepsinogen may prove useful in the diagnosis and possibly in the prediction of duodenal ulcer.

The present article reports an effort to determine whether certain specific ethnic groups in the population differ significantly in their serum pepsinogen level. This study is preliminary to future analysis of relationships between elevated pepsinogen level, duodenal ulcer, and personal and social factors. The relationships may indicate how further investigation of pepsinogen and ulcer should proceed. Reports on the relation of ethnic origins and pepsinogen to duodenal ulcer are rare in the literature for this is a recent line of inquiry. The incidence of ulcer in various nations and racial groups has been reported,<sup>3-6</sup> however, differences in methods and in thoroughness of compilation preclude extended comparison.

### METHOD

Two thousand newly inducted soldiers were chosen at random from the processing center at Fort Dix, N. J., during an eight week period in the fall of 1954. All were young men who had recently been subjected to several physical examinations and were presumed to be in good health. Their mean age was 21.1

years. As new basic trainees all were faced with the stresses and uncertainties involved in military induction.

Of the total sample of 2,000 men 1,900 qualified for inclusion in the present study by fulfilling these criteria: (1) All were born in the continental United States, (2) each contributed a blood sample which was analyzed for pepsinogen, and (3) each completed a sociologic questionnaire designed by the author. From this number the selection of ethnic subpopulations was made.

Blood samples were sent daily for determination of plasma pepsinogen levels. A numerical "pepsinogen score" was obtained by expressing the proteolytic activity of the plasma as micrograms of "tyrosine" released by the action of 1 ml of plasma at pH 1.5 in the standard assay procedure.

The sociologic questionnaire consisted of items dealing with the social background of the inductee, his parents and his grandparents. Both the blood samples and the sociologic questionnaires were identified by code numbers. Sociologic material and the pepsinogen scores were held separate until the final phase when both sets of information were transferred to IBM cards.

Ethnic groups were differentiated solely on the basis of operationally defined traits. Those inductees who on the sociologic questionnaire identified both parents as being of a specified ethnic origin were included in that group. Inductees who recorded the religion of both parents as Jewish at birth were included in the Jewish sample, and men who listed both parents as of the Negro race were classified as belonging to the Negro sample. The Negroes are obviously a racial group, but for the sake of brevity, the term "ethnic group" is used throughout this article for the Negro as well as for the other four subpopulations.

Five groups were selected. In order of size they were of the following origins: Jewish (347), Italian (302), Irish (212), German (91), and Negro (64). They totaled 1,016 men representing an approximate 50 per cent of the original random sample. The majority of inductees, with the exception of the Jews and Negroes, reported that three or four of their grandparents were born in the specific country of national origin, with the remainder reporting that at least one grandparent was born there. The majority of Jewish inductees also recorded the European birth of all four grandparents. The Negroes were the only men whose grandparents were virtually all of native American birth.

The locale where the research was done, Fort Dix, N. J., affected the ethnic composition of the sample. Men processed

through Fort Dix are primarily from the northern United States, an area in which a variety of recent immigrant groups are concentrated.

A large proportion of the sample, moreover, was made up of men from urban centers of population, 42 per cent, for instance, were from New York City. Less than 2 per cent came from rural or farm areas. Eighty per cent of the total sample came from two states, New York and New Jersey, with the majority of the remaining men originating in New England states.

The entire sample of 1,900 men for whom data on both pepsinogen and social background were available was classified into deciles in terms of pepsinogen level. From the total population the five special groups of inductees were selected by means of criteria already described. The distributions of scores for these groups were then subjected to statistical analysis.

### RESULTS

When the mean scores for one of the ethnic groups are examined, differences in elevation of pepsinogen level are apparent. In table 1 the groups are ranked in terms of size of the mean. The mean for the Irish inductees is the highest, while the Italians and Jews are the two lowest groups in terms of mean pepsinogen score. The range between means for the Irish and Jewish groups is from 422 to 518 points, a difference of almost 100. The difference between the highest mean, the Irish, and the second highest, the Negro, is a spread of 68 points. On the other hand, with the exception of the Irish means of all the groups are clustered within a range of 28 points; the range between the means of the Jewish and Negro groups.

TABLE 1 *Plasma pepsinogen levels of ethnic groups*

Nationality	Number in sample	Mean plasma pepsinogen	Standard deviation	Level of significance of F ratio when compared with Irish
Irish	212	518	226.6	Not significant $p < 0.01$ $p < 0.001$ $p < 0.001$ $p < 0.001$
Negro	64	450	219.5	
German	91	444	188.5	
Italian	302	432	199.3	
Jewish	347	422	179.0

Five groups were selected. In order of size they were of the following origins: Jewish (347), Italian (302), Irish (212), German (91) and Negro (64). They totaled 1 016 men, representing an approximate 50 per cent of the original random sample. The majority of inductees, with the exception of the Jews and Negroes, reported that three or four of their grandparents were born in the specific country of national origin, with the remainder reporting that at least one grandparent was born there. The majority of Jewish inductees also recorded the European birth of all four grandparents. The Negroes were the only men whose grandparents were virtually all of native American birth.

The locale where the research was done, Fort Dix, N. J., affected the ethnic composition of the sample. Men processed

ences in the birthplaces of grandparents or parents did not significantly affect pepsinogen scores for the Irish group

**Relation of Social Variables to Pepsinogen Levels** In the literature on ulcer a number of studies cite social variables such as occupation, mobility, family structure, and other factors as being of significance.<sup>8-14</sup> In the light of these writings, an effort was made to test the significance of a number of variables in the total sample population and within each of the three largest groups, the Irish, Italians, and the Jews. On the assumption that a high pepsinogen level implies particular proneness to duodenal ulcer, the purpose was to determine whether men in certain broad social groupings or social situations might have higher scores than others. The Index of Status Position and an occupational scale devised by Professor August B. Hollingshead of the Department of Sociology, Yale University, were used.

The following items were examined in relation to pepsinogen level: (1) occupation of the inductee before entering the Army, (2) educational level of the inductee, (3) occupation of the father, (4) social class of the father, (5) occupational ambitions of the inductee in relation to his father's occupation as an index of mobility, and (6) differences between parents and the inductee regarding the occupational ambitions of the youth. No significant statistical relationships were found. The negative results indicate that (1) either no relationships exist between pepsinogen level and the individual variables examined or (2) the techniques used were not sufficiently sensitive to detect such a relationship.

### COMMENTS

While the Irish inductees were found to have significantly higher pepsinogen scores than the other groups, the meaning and implications of the results are not clear. Obviously, it is not simply the fact of being of Irish national origin which underlies the results, but rather that the Irish have certain traits in common more than any other group in the sample. These traits presumably are causal or influential in producing elevated levels of plasma pepsinogen. The literature contains a wide variety of hypotheses concerning the origins of ulcer, ranging from theories on genetic, constitutional, dietary, neurologic and endocrine factors, to explanations in terms of emotions and the unconscious mind. Within this theoretical setting the precise identification of the variables which lead to high pepsinogen levels is an additional area for rigorous empirical work.

Replication of research is a basic principle in the development of theory in science. In the present study, the development of theory is hindered by the lack of replication.

the groups particularly the Negro group, makes repetition of the study desirable. However, since the exploratory work indicates significant differences between certain groups it is possible for future investigations to concentrate on underlying variables while at the same time duplicating the study.

Because the Irish appear to be a special group in terms of plasma pepsinogen the research might conceivably be repeated with comparative ease in Ireland where large samples are available. The essential test of measuring plasma pepsinogen can be set up as a routine matter of laboratory procedure. Similarly research might be performed in Italy and among Jews of eastern European origin in Israel as these represent groups with low mean levels of pepsinogen.

One of the ultimate aims of research in this area is the validation of the proposition that high pepsinogen level is an indication of the likelihood of developing duodenal ulcer. Accordingly an ideal study would be concerned with the actual incidence of ulcer within subcultural groups which exhibit elevated plasma pepsinogen levels. Either a longitudinal approach or a latitudinal study with selected age levels might be used. From multidimensional research answers may emerge to clarify some of the current medical problems and controversies concerning the origins, course, and therapy of duodenal ulcer.

### SUMMARY

Comparisons of plasma pepsinogen levels in five operationally defined ethnic groups were made in order to determine differences in pepsinogen score. The underlying assumption based upon reports in the literature was that elevated levels of blood pepsinogen are indicative of a tendency to develop duodenal ulcer. The five groups consisted of 1,016 Army inductees who passed through the processing center at Fort Dix, N. J.

The mean pepsinogen score of the inductees of Irish origin was the highest of the five groups, differing significantly from the scores of the German, Italian, and Jewish men. The Negro group, however, stood in an intermediary position between the Irish and the others, differing significantly from none of them. Lowest pepsinogen level scores were found among the Italian and Jewish inductees. The implications of the results were discussed with emphasis on the advisability of repeating the study in the individual countries of national origin.

## Problems in Control at a Recruit Training Base

BERNARD M REEN *Captain USAF (MC)*

NORBERT SCHALET *Captain USAF (MC)*

HAROLD B HOUSER *M D*

**T**HE EXACT nature of the well known relationship between group A streptococcal infections and rheumatic fever has not been established. In a recent discussion of the pathogenesis of rheumatic fever McCarty<sup>1</sup> pointed out many of the unanswered problems concerning the role of the streptococcus. Fortunately although these problems exist preclusion of rheumatic fever by either prophylaxis or adequate therapy of streptococcal infections is well recognized. The principles of prevention of recurrent rheumatic fever are well accepted and practicable; however, they are more difficult to apply for the prevention of initial attacks.

As shown by studies at the Streptococcal Disease Laboratory, Francis F. Warren Air Force Base, Wyo.,<sup>2,3</sup> first attacks of rheumatic fever can be prevented when the preceding streptococcal infections are adequately treated with penicillin or broad spectrum antibiotics. Hubbard<sup>4</sup> recently discussed the difficulties of preventing initial attacks in the general population and suggested that the "captive population" at a military installation would be an ideal group in which to treat acute streptococcal infections for prevention of rheumatic fever.

Experience at Sampson Air Force Base during the winter of 1954-1955 has shown that even in a military population, prevention of first attack rheumatic fever by treatment of streptococcal disease leaves much to be desired. This article outlines

---

From Laboratory on Housing and Illness, Armed Forces Epidemiological Board, and Department of Medicine, State University of New York, Upstate Medical Center, Syracuse, N. Y., and Preventive Medicine Section, U. S. Air Force Hospital, Sampson Air Force Base, N. Y.

This investigation was conducted under sponsorship of the Committee on Acute Respiratory Disease, Armed Forces Epidemiological Board. It was supported by the Office of the Surgeon General, Department of the Army and Air Force and in part by funds provided under contract with the U. S. Air Force School of Aviation Medicine, Randolph Field, Tex.

some of the difficulties in such a program and the specific measures employed at this base to reduce the incidence of rheumatic fever

### MATERIALS AND METHODS

Simpson Air Force Base, situated in an endemic streptococcal region in central New York State, was a primary basic training base for recruits. The average trainee population varied from 10,000 to 22,000 men.

A throat culture was obtained from all patients admitted to the base hospital with respiratory disease. Strains of beta hemolytic streptococci isolated from these cultures were identified by Lancefield group and type.

The hospital charts of all patients with a discharge diagnosis of acute rheumatic fever with an onset between 4 November 1954 and 1 August 1955 were reviewed. The diagnostic criteria employed in this review were those of Jones,<sup>4</sup> with evidence of recent streptococcal infection as an additional minor criterion. Admittedly, some cases of acute rheumatic fever with mild manifestations were excluded, but the application of these criteria assured us of a measure of uniformity in the series.

In order to include only patients with rheumatic fever who were likely to have developed their preceding streptococcal infections at this base, cases of rheumatic fever occurring less than 10 days after a man's arrival were excluded. In addition, no rheumatic fever patients received here by air evacuation from other bases were included. Permanent party personnel from this base were not included in the analysis.

### RESULTS

Of 122 discharge diagnoses of rheumatic fever during the study period, 98 met our criteria and are included here. Seventeen of the remaining 24 probably were rheumatic fever with mild manifestations. The other seven were excluded as permanent party, air evacuees, or on the basis of a different diagnosis. The time of onset of the disease in the 98 patients was ascertained from the recorded history and is presented in figure 1.

The hospital admission rate of patients exhibiting ten or more colonies of group A streptococci on admission throat culture is shown in figure 2. Although some of these persons may have been carriers, it is thought that in most instances the admission was for streptococcal pharyngitis. The predominant type of group A streptococcus throughout the study period was 19

Examination of figure 2 shows that the rate for streptococcal pharyngitis rose rapidly

Figure 1 The occurrence of acute rheumatic fever at a recruit training base November 1954 to August 1955

Figure 2 Hospital admission rates for streptococcal pharyngitis and rheumatic fever at a recruit training base November 1954 to July 1955

to a peak of 12.5 cases per week per 1,000 men dropped remarkably in late December coincident to the Christmas and New Year's leave period, and then rose rapidly to a peak of 11.3 by 26 January. At this point penicillin prophylaxis was ad-

ministered on a base wide scale, and the rate dropped off precipitously. The results of this prophylaxis will be presented in detail elsewhere.<sup>7</sup>

The rate began to rise again in the early weeks of March and reached a peak of 12.7 by early April. This rate was sustained until mid June and thereafter fell off to negligible levels for the summer.

The coincident rate of rheumatic fever is also presented in figure 2. It can be seen that the rate rose with the increased hospital admissions for streptococcal disease, reaching a peak of 70.2 cases per week per 100,000 men by 12 January 1955, and fell off at the time of penicillin prophylaxis. Two weeks after the streptococcal rate again began to rise, the incidence of rheumatic fever began to increase. Although the streptococcal hospitalization rate again reached proportions similar to those earlier in the season, the concomitant rise in rheumatic fever was less than earlier. The reasons for this observation merit close scrutiny.

#### DISCUSSION

Several possible explanations for the failure of the rheumatic fever rate to parallel the streptococcal rate in the second half of our reporting period present themselves. The factor of host susceptibility to beta hemolytic streptococcal infections has long been discussed. Certainly some families have a higher rheumatic fever incidence than the normal population, and the tendency of rheumatic fever subjects to have recurrences of their disease is well recognized. These people might then be considered to have an increase in host susceptibility to rheumatic fever. Without debating the point of familial factors in rheumatic fever, they would seem to be of little importance in explaining the difference in rheumatic fever response to the streptococcal rates in the two periods of our series. In a population as large and heterogeneous as that dealt with at a military training base, the proportion of susceptible persons should be similar at any time throughout the year. As far as recurrent rheumatic fever is concerned, such cases accounted for proportionately as many admissions in the period before penicillin prophylaxis as in the period after it.

The effect of season on the incidence of rheumatic fever might be a factor in the observed differences, but the weight of evidence indicates that the seasonal variation merely reflects the seasonal incidence of streptococcal infections.<sup>8</sup> Another explanation of the observed variation might be the presence of a particularly virulent rheumatogenic strain of streptococcus in

the early part of the winter. This seems unlikely in view of the fact that there was no type change in the streptococci responsible for disease during the two periods. In addition there is little evidence that group A strains vary in their rheumatogenic capacity. We believe that the disparity in the streptococcal and rheumatic fever rates during the second half of the winter can be explained best as the result of specific measures which were instituted.

It must be remembered that these streptococcal rates represent only hospital admissions and are not a true measure of the total streptococcal disease on the base. If we assume that the patients with streptococcal disease recognized in the hospital were adequately treated then we can expect up to 90 per cent reduction in the development of rheumatic fever in this group. In fact, only 3 of the 98 patients with rheumatic fever seen during the winter had been hospitalized for a preceding streptococcal infection. Of these, two had received three and four days of penicillin therapy, respectively while the third had not received any penicillin. We believe that the remainder of the patients with rheumatic fever seen during the winter had had streptococcal infections that were undiagnosed and untreated or if diagnosed were inadequately treated without admission to the hospital.

If as is generally accepted about 3 per cent of untreated patients with group A streptococcal infections will develop rheumatic fever<sup>10</sup> then any given group of patients with rheumatic fever can be considered to be 3 per cent of the total number of those who had undiagnosed or inadequately treated streptococcal infections 2 to 3 weeks prior to the onset of the rheumatic fever. From this assumption, it is then possible to estimate the total number of cases of streptococcal disease present in a group. Figure 3 shows a comparison of the hospital admission rate in this series with the assumed incidence of streptococcal pharyngitis among the total recruit population. The assumed rate was calculated by adding to the hospitalization figures the number of cases that must have occurred to account for the rheumatic fever that developed. To allow for the latent period the cases assumed to have occurred to account for the incidence of observed rheumatic fever have been moved back two weeks from the time of onset of the rheumatic fever.

It can be seen from figure 3 that during the weeks prior to penicillin prophylaxis a great many cases of streptococcal infections were either not recognized or inadequately treated on a dispensary level. Little more than one quarter of the estimated cases of streptococcal disease reached the hospital whereas

after the period of penicillin prophylaxis, over 50 per cent of the estimated streptococcal cases were hospitalized and adequately treated

Figure 3 Hospital admission rate and assumed total rate for streptococcal pharyngitis in recruits, November 1954 to July 1955

We believe that several factors, some of which are peculiar to a military population, were responsible for this increase in the detection and treatment of streptococcal disease

1 The tendency of the trainee with minor respiratory complaints to refrain from reporting to sick call accounted for many of our untreated streptococcal cases. This is illustrated in figure 2, where the streptococcal hospitalization rate fell so precipitously during the period approaching the Christmas and New Year's leave time. Perhaps a decrease in population with a decrease in exposure rates could account for some of this decline, but the absence of a decrease in rheumatic fever and the decline in admissions before leaves actually began indicate that this was not an important factor. The decrease in hospitalization rate for streptococcal infections must be attributed largely to the reluctance of the trainee to present himself on sick call and face possible hospitalization in lieu of the holiday leave.

During the early weeks of January, an intense educational campaign was initiated to encourage the trainee to appear at sick call when even minor symptoms occurred. It is believed that as a result, many streptococcal infections were seen, diag-

nosed, and treated which would otherwise have run their natural course as mild untreated cases

2 A second and probably more important factor was the improper treatment of recognized streptococcal cases. This became evident from interviews with patients hospitalized with rheumatic fever. In several instances, the correct diagnosis had been made but the prescribed course of therapy was too short to prevent the nonsuppurative complications. Present evidence indicates that eradication of the infecting organism from the throat is necessary if rheumatic fever is to be prevented.<sup>10</sup> For the most effective eradication of the streptococcal organism, penicillin blood levels must be maintained over a 10 day period.<sup>11</sup> This was re-emphasized to all medical officers.

A practical therapeutic problem in the protracted treatment of streptococcal infections on a dispensary level lies in the tendency of the trainee to be governed by his symptoms. He will be told to return for additional penicillin injections or to continue taking penicillin by mouth for 10 days, but all too frequently with the subsidence of his acute symptoms he will discontinue therapy after 3 to 4 days. This sequence of events accounted for a considerable portion of rheumatic fever in the early part of the winter. This was eventually corrected by admitting patients with streptococcal infections to the hospital for treatment.

3 The last and we believe the most important factor in curbing the untreated streptococcal rate, was the institution of a policy whereby all patients who fulfilled the criteria of a temperature of 100°F or above or who had purulent pharyngitis regardless of temperature were admitted to the hospital. It has been pointed out by many that if only the clinical case which presents the classical picture of streptococcal pharyngitis is treated an alarming proportion of streptococcal disease is missed. Breeso and Disney<sup>12</sup> stated an accuracy of diagnosis on clinical grounds of 75 per cent in both positive and negative cases when checked against bacteriologic cultures. It is our experience that this degree of accuracy can hardly be expected at an installation such as this. Ideally a system of throat cultures for suspected cases must be instituted.

By admitting all patients who fulfilled these criteria of elevated temperatures or purulent pharyngitis we were able to obtain throat cultures and retain those with streptococcal disease in the hospital for a course of penicillin therapy. Long acting penicillin in large enough quantity was not available to us at that time. Had it been available a throat culture system on out-patient status with one injection of benzathine penicillin would

1-1-1947

## EPIDEMIC RHEUMATIC FEVER

have been instituted. This should be an equally effective less expensive method of detection and treatment of streptococcal disease.

With the limitations imposed by the lack of a single penicillin treatment for streptococcal disease, the practice of hospitalization proved valuable in reducing the untreated streptococcal disease rates and in preventing many cases of rheumatic fever. However even in our "captive population" and in special emergency treatment of recognized streptococcal disease cases of rheumatic fever still occurred in the postprophylactic period. Prophylaxis of streptococcal infections thus seems to be the only practical way at present to reduce the incidence of rheumatic fever to a satisfactory rate.

I still remain of the opinion of the physician to recognize streptococcal infections so that an incipient epidemic is apparent and prophylaxis can be instituted without delay. The physician should not wait until the occurrence of many cases of rheumatic fever alerts him to the presence of a streptococcal epidemic.

## SUMMARY

The problem of controlling streptococcal disease and rheumatic fever is a large military installation is not at all simple. To effect a large-scale program for adequate prevention of the consequent complications of streptococcal disease co-operation for many sources is requisite.

It should be continually borne in mind that satisfactory eradication of the streptococcus is more a factor of the duration of medication with penicillin than of the amount administered.

Trainees should be improved with the necessity of appearing as sick call for even minor throat and respiratory complaints.

Because of difficulty in effecting the return of the ambulatory trainee for further penicillin therapy after his symptoms have subsided, best results can be obtained by treating persons with streptococcal pharyngitis in the hospital except that if benzathine penicillin is available, hospitalization probably is not necessary for the treatment of persons with mild infections.

By instituting more strict criteria for the hospitalization of patients with respiratory disease, many cases of streptococcal infection in our camp, which would otherwise have gone unrecognized, were discovered and treated with a long-acting one injection treatment. It has been available and the result as we obtained with hospitalization could have been expected.

on an outpatient basis by taking cultures from the throats of all those who met these criteria

# BEGINNINGS OF A THERAPEUTIC COMMUNITY

Establishing Group Meetings on a Closed Ward

FRANK L RUNDLE *Lieutenant MC USNR*  
DENNIE L BRIGGS *Lieutenant MSC USN*

THAT the closed admission ward of a psychiatric service in a military hospital can be operated as a "therapeutic community" in accordance with the principles of social psychiatry developed in England,<sup>1</sup> has been demonstrated and reported by Wilmer.<sup>2,3</sup> He described his experiences in operating an acute admission ward without use of traditional suppressive and restraining measures, particularly quiet rooms and sedation. The results were impressive and the prospect of using similar methods under other circumstances was appealing. It seemed that such a method of ward management and patient treatment would be ideally suited to the operation of the closed ward in this overseas naval hospital.

Having had no experience in group therapy and lacking more detailed information than that appearing in Wilmer's article, the senior author, who was Ward Medical Officer, was reluctant to initiate such an undertaking. However, with the aid of the junior author, who was a clinical psychologist and had had such experience, the program of establishing the closed ward as a therapeutic community was begun. In this article some of the practical problems involved during the first six weeks of that program will be discussed.

## INITIAL CONDITIONS

The physical arrangement of the closed ward presented great disadvantages, as it had not been originally planned as such and the facilities were far from adequate. The ward was long and narrow with a capacity, including three quiet rooms of 33 patients. There was a small enclosed courtyard at the rear where patients could play basketball and volleyball. Patients were not allowed off the ward except in the custody of a corpsman and at the spe-

---

From the U S Naval Hospital Yokosuka Japan

cific order of a medical officer Except for playing hall and a daily movie on the ward, the only entertainment and recreation for the patients was provided by the Red Cross

Prior to the initiation of the therapeutic community program nurses were not regularly assigned to the closed ward Usually the nurse on an adjacent ward covered the closed ward as well being there only briefly to dispense medications and care for administrative details At nights it was covered by the supervisor who usually had six wards to cover

The hospital corpsmen on the ward had had no formal training in the care of psychiatric patients or in the management of a psychiatric ward All had volunteered to work on the neuropsychiatric service Most of them were basically friendly and understanding in their dealings with patients, but there were some who were so insecure and felt so threatened that they needed to use means of physical restraint

This is the only fully staffed naval hospital West of Guam and serves naval and Marine Corps personnel in Korea Japan Okinawa Formosa and aboard ships operating in the encompassed areas The average monthly psychiatric admission rate is about 70 patients Patients frequently arrive without prior consultation with our staff hence many are admitted when consultation would suffice Frequently high prisoners from the surrounding activities are sent for admission for little other reason than not being able to accept their status as prisoners Sometimes of necessity acutely intoxicated and disturbed individuals are admitted to the ward overnight because there is no other place to put them Frequently persons involved in administrative or legal action because of homosexuality are admitted for administrative reasons Patients who have made a suicidal gesture or attempt are usually common due to special factors and circumstances in the Far East

All the above factors caused the ward population to be extremely heterogeneous and often difficult to manage and adversely affected therapeutic aims in some instances

### INITIATING THE NEW PROGRAM

The only preparations made for initiating the "new regime" as it came to be known were these (1) The bunks on the ward were rearranged so a large enough area could be provided for the patients and staff to be seated in a circle (2) The corpsmen were told that we were about to try something new in the way of ward management and that the objective was to abolish suppressive techniques and place as much responsibility as possible for control and management upon the patient both individually and

collectively (3) Patients and staff were informed that a meeting would be held on the ward every morning except Sunday and that everyone would be expected to attend

There were 26 patients on the ward when the new program began. Those patients had been on the ward in some instances for only a day, and in one case for six months. Twelve patients were diagnosed as schizophrenic, 3 as having a neurotic depressive reaction, and 1 as having an anxiety reaction. The remaining 10 were classified as having character and behavior disorders.

**Plan of the Day** The working day on the ward began at 0745 hours when the staff doctors and nurse interviewed newly admitted patients. Sick call followed, and the group meeting took place soon thereafter and lasted 45 minutes. A staff meeting followed the patient meeting, in which the group meeting was analyzed and pertinent information about the behavior of the patients on the preceding day was discussed. A report from the night corpsmen was made known to the staff.

**The First Group Meeting** For the first meeting, the physician, the clinical psychologist, the nursing supervisor, a recently assigned ward nurse, 2 Red Cross workers, the master at arms, 6 hospital corpsmen, and 23 patients were gathered in a circle in the rear of the ward. Three patients absolutely refused to attend the meeting.

The meeting was opened by the Ward Medical Officer who stated that the group would meet daily six times per week for 45 minutes, and that all present were invited to use this opportunity to express their feelings about the way the ward was run, to ask questions, and to bring up any personal problems with which they desired help.

The first patient to speak was the one who had been on the ward the longest (six months) and who was tacitly recognized as the leader by most of the patients. This patient asked why the radio couldn't be located at the rear of the ward rather than at the nurses' station and why the corpsmen considered it dangerous to have it in the limited recreation area. One patient, half sarcastically and with insight into some of the staff's attitudes remarked, "We are all emotionally unstable and can't be expected to control ourselves," and then got up and nervously paced the floor for the remainder of the meeting. Another patient declared to the group that now that a nurse would be regularly assigned to the ward, the patients would have to watch their language. At another time a patient asked if a quiet hour could be observed, and after considerable discussion by the group it was decided that due to weekday activities such a quiet hour could be observed only on Sundays.

cific order of a medical officer. Except for playing ball and a daily movie on the ward, the only entertainment and recreation for the patients was provided by the Red Cross.

Prior to the initiation of the therapeutic community program nurses were not regularly assigned to the closed ward. Usually the nurse on an adjacent ward covered the closed ward as well being there only briefly to dispense medications and care for administrative details. At nights it was covered by the supervisor, who usually had six wards to cover.

The hospital corpsmen on the ward had had no formal training in the care of psychiatric patients or in the management of a psychiatric ward. All had volunteered to work on the neuropsychiatric service. Most of them were basically friendly and understanding in their dealings with patients but there were some who were so insecure and felt so threatened that they needed to use means of physical restraint.

This is the only fully staffed naval hospital West of Guam and serves naval and Marine Corps personnel in Korea, Japan, Okinawa, Formosa and aboard ships operating in the encompassed areas. The average monthly psychiatric admission rate is about 70 patients. Patients frequently arrive without prior consultation with our staff hence many are admitted when consultation would suffice. Frequently brig prisoners from the surrounding activities are sent for admission for little other reason than not being able to accept their status as prisoners. Sometimes of necessity acutely intoxicated and disturbed individuals are admitted to the ward overnight because there is no other place to put them. Frequently persons involved in administrative or legal action because of homosexuality are admitted for administrative reasons. Patients who have made a suicidal gesture or attempt are unusually common due to special factors and circumstances in the Far East.

All the above factors caused the ward population to be extremely heterogeneous and often difficult to manage and adversely affected therapeutic aims in some instances.

#### INITIATING THE NEW PROGRAM

The only preparations made for initiating the new regime<sup>o</sup> as it came to be known were these: (1) The bunks on the ward were rearranged so a large enough area could be provided for the patients and staff to be seated in a circle. (2) The corpsmen were told that we were about to try something new in the way of ward management and that the objective was to abolish suppressive techniques and place as much responsibility as possible for control and management upon the patient both individually and

require every patient to attend. We then found that those who formerly refused would attend without overt resistance. It appeared that an important part in their subsequent change in attitude was due to our providing them with an acceptable reason to save face and join the community, which apparently they had wanted to do all along.

The problem of attendance at meetings now rarely causes difficulty, but when it does come up with individual patients, it always has significance and is brought up in the meetings. Once in a while, if a patient refuses to attend, the group waits for him and the leader does not allow the meeting to proceed until all are present. The other patients will usually convince the patient that he should be there, an appeal to courtesy and good behavior is frequently all that is necessary.

**Seating** The area used for the meetings should be fairly small so as to encourage patient and staff to sit close to each other and to allow each to be visible to all. This in itself fosters social control as each member of the group is under scrutiny by all others. Despite all efforts to maintain group solidarity in seating, some patients and staff tend to occupy positions indicative of their resistance or need to avoid scrutiny. Permitting persons to sit on table tops, on the floor, and behind objects allows them to remain outside the group physically as well as psychologically and to escape being members of the group. It is desirable for the staff to disperse themselves in the group to meet the immediate needs of the patients, however, it was often obvious that they placed themselves in accordance with their own needs.

If a patient is resistive or upset, a staff member may personally extend an invitation to the patient to sit by him in the meeting. Initially some of the staff did not sit, but stood in the fringes of the group. After repeated fruitless discussions in staff meetings this matter was finally resolved simply when the leader on one occasion offered a corpsman his chair. We believe that the leader should sit in the same position at each meeting but that the rest of the staff should distribute themselves throughout the group. The patients soon seem to reserve the same position for the leader and we believe it symbolically provides some bit of security upon which the insecure patient can depend. On one occasion when the leader had to be absent from the meeting, the senior corpsman carried on the meeting, sitting in the leader's chair, which resulted in the expression of good natured indignation.

**Time** Our groups met for 45 minutes 6 days per week, and we adhered to the beginning and ending times quite strictly. At

The general tone of the meeting was lively and at times several persons spoke at once. In addition there was laughter and sarcasm, and some patients held private conversations with other patients and with staff members. The Ward Medical Officer interceded to encourage order and recognition of a single speaker. Throughout the meeting there was a display of real interest in improving ward conditions, but the revealing of personal feelings and problems was minimal.

Afterward the staff assembled in a small office on the ward and recounted the events of the meeting just held. The ward physician, psychologist, and nurses felt encouraged and optimistic, but most of the corpsmen seemed skeptical. The corpsmen later explained that they initially believed their position of authority and means of control of the patients were in jeopardy.

**Subsequent Group Meetings.** In the succeeding weeks the group meetings continued to develop in the direction of open and free discussion. Initially considerable time was spent in questioning and evaluating past restrictive measures and in some cases deciding to change them. Immediate interpersonal entanglements, both between patients and between patients and staff, were more freely aired as time passed. As the atmosphere of receptiveness and tolerance of discussion developed more and more problems of an inner personal nature were introduced. At the end of six weeks the period covered by this article the group meetings were effectively utilized in working out difficulties between individuals, problems of ward management, and personal problems of considerable intensity and importance.

### IMMEDIATE PROBLEMS

The following points that arose in the first six weeks of operating the closed ward as a therapeutic community are considered to be of importance for others who might be interested in starting such a program but who are lacking in experience, as was the senior author. Some of the errors made in beginning this undertaking, from the standpoint of the mechanics of running the daily groups, will be discussed.

**Attendance.** We did not insist initially that every patient attend the meetings, but strongly urged them to do so, stating that we expected everyone to attend. We found that attendance must be required in the operation of a community type treatment program as the feelings and behavior of every patient and staff member influence the others. We found that those patients who refused to attend thus not allowing their attitudes and actions to be considered and inspected by the community were those who caused the most difficulties on the ward. We eventually realized that we had to exercise our military prerogative as officers and

tant single treatment procedure for the day and required that the staff participate as a treatment team and attempt to hold possible distractions to a minimum. The group leader should never answer the telephone or leave the group meeting, except in absolute emergency. He should allow no staff member or patient to leave except if unavoidable. Patients always noticed closely which staff members attended and often commented on their presence or absence both during the meetings and outside them.

**Withdrawal** Except in rare instances, patients were not permitted to withdraw or leave the group. If a patient became angry and left the group we waited to see if another patient would attempt to retrieve him, if not, a staff member would try. If these means were not successful, the leader would always go after the patient, and in few instances has a patient refused to return. When he returned, the matter was discussed and the group attempted to help him control himself and his anger more adequately. In one instance, an aggressive, angry patient made a lunge for the door as a corpsman was opening it, making loud angry statements to the group. A nurse, with no prior training or experience in psychiatry, went after the patient and brought him back to the group and held his arm gently for the remainder of the meeting. Previously his scuffles had required several corpsmen to help him gain control of himself.

**Aggressive Behavior** Occasionally, tempers flared and erupted and patients verbally or more rarely physically (once during this period) attacked other patients. A sharp verbal attack can usually be handled by promoting ventilation and making interpretations of obvious factors involved. Physical violence must, if necessary, be physically constrained by the staff in a matter of fact, nonhostile manner, then, if possible, the person's feelings should be discussed.

**Relaxation of Old Restrictive Measures** A great part of the initial group discussions concerned the questioning and re-evaluation of old restrictive measures such as are practiced on most closed psychiatric wards. As much as was possible, the group was encouraged to arrive at their own decision as to whether such measures were any longer necessary. However, in some cases the medical officer found it necessary to contradict group opinion and decision concerning such matters, because of administrative necessity or because of his own philosophy of treatment. Events subsequent to the period with which this article deals demonstrated that external control measures can be safely relaxed only gradually as patient group solidarity and acceptance of responsibility for individual actions are developed. Perhaps it would be even more important that the staff feel confident and unthreatened by changing of security measures.

## SUMMARY AND CONCLUSIONS

Some of the immediate problems encountered in the initial phases of establishing a therapeutic community type of management and treatment on a closed psychiatric ward in an overseas military hospital have been discussed. This article was prepared to give others who are inexperienced in methods of community therapy some idea of the more concrete problems arising in the undertaking.

The immediate goals in using the therapeutic community approach were to (1) improve ward management by dealing openly with patient staff tensions and resentments and the adjustment of patient staff roles and relationships which this involved, (2) prepare patients for continued treatment and hospitalization by acculturating them to the hospital (3) promote realistic acceptance by patients of their roles as patients, and (4) encourage patients to take an active part in their own treatment and that of other patients. These goals have been attained in general.

Through the therapeutic community method, the number of acute management problems occurring on the ward has been greatly reduced and except for occasional use of the quiet rooms for acutely disturbed drunk patients the need for restraint has been entirely eliminated. Informal communications received from other hospitals to which some of our patients have been evacuated indicate that many of them take their hospitalization more seriously and work harder in their treatment than do patients from most hospitals. In some instances they reportedly assisted the other patients in learning to accept their status. Long range plans for using this method of treatment at this hospital include development of procedures for returning more patients to duty from this command and improving the condition of those who require evacuation to the United States for further treatment.

It is possible by applying therapeutic community techniques to materially improve the over all quality of patient care particularly as regards socio environmental aspects of treatment, on the psychiatric service in a military hospital not designated a "treatment center." It appears that continued use of traditional suppressive management because of inadequate facilities lack of trained staff and rapid turnover of patients is not justifiable considering that all these disadvantages were initially present in this case and did not prevent the successful use of the therapeutic community method. Of primary importance in an undertaking such as described herein is that the staff have a sincere interest in and a genuine desire to help people. Specialized technical training is not essential although provisions for training ward personnel within the program are important. Absolutely

essential is a general attitude on the part of the staff which embodies kindness, understanding, sincerity, and an unflinching conviction of the worth and dignity of the human being

#### PSYCHOLOGY OF HIGHWAY SAFETY

"Understanding and possibly controlling the human factors of drivers (e g their attitudes and personal adjustments) as well as the driver's equipment and environment (e g the design of his automobile) provide the most promising areas to prevent automobile accidents. Though no single characteristic of drivers has yet been isolated that appears to be outstanding in accounting for the large proportion of accidents on the highways there do appear to be several etiological groupings. One of these is the accident repeater who may manifest general instability in society or even possess a mild psychopathic personality. As in the control of other epidemics we must find means of identifying the most important variables relating to the "host," as well as the "agent" and the environment. Physicians can play an important role in such an approach."

# NONSPECIFIC PROSTATOURETHRITIS

ARTHUR N TESSLER *Lieutenant MC USNR*

JESSE F RICHARDSON *Captain MC USN*

**N**ONGONOCOCCAL urethritis is the term used in recent literature to describe the presence of a urethral discharge not associated with intracellular diplococci of gonorrhea.

It has also been called nonspecific, or less commonly, nonvenereal urethritis. Its etiology, pathogenesis and pathology is but partially understood.

The discharge is most frequently mucopurulent or milky, but varies from frankly purulent to mucoid. It varies from profuse to scant and usually is associated with dysuria of varying degrees, particularly in or near the urethral meatus. Less frequently the patients complain of frequency, urgency, and pain in the perineum. Microscopic examination of the discharge reveals pus cells and bacteria, usually gram positive,<sup>1</sup> in various concentrations.

Treatment of this condition is empirical and clinical relapses have plagued all military medical officers. There are many reasons for delay in better understanding of this misnamed disease but some of them can be overcome. We wish to relate our experiences with this disorder, suggest improvements in therapy, and to suggest new methods of study.

## INCIDENCE

It is impossible to report the accurate incidence of this disease because it is not a reportable disease in most areas. Only since 1952 has it been a reportable disease in the United States Navy. During the years 1953 to 1955 approximately 20,000 cases have been reported annually in the Navy and Marine Corps.<sup>1</sup> This represents approximately 2 per cent of the men in the services. Interpolated for the remaining services, the resultant figure re-emphasizes the magnitude of the problem for this non-serious "entity."

From the number of articles on the subject originating within the medical departments of the armed services compared with the scarcity of both articles, and apparently cases, from our

---

From U S Naval Hospital St Albans Long Island N Y Dr Tessler now at  
4 Bayside Drive Great Neck N Y

civilian population, we must infer that something inherent in military life is important in the etiology of this disease. Two thirds of the cases reported in the Navy and Marine Corps<sup>2</sup> were personnel assigned to ships, 28 per cent were men stationed in noncontinental United States stations, and 7 per cent were men in the continental United States. The incidence among shipboard personnel was from 3 to 4 per cent, among personnel at overseas stations, 4 per cent, and among men in the States, the incidence was 0.3 per cent. The incidence varies geographically, but it is so universal as to rule out a "vector of limited geographical habitat."

### ETIOLOGY AND PATHOGENESIS

One cannot fail to be impressed with the concept of venereal transmission of nonspecific prostatourethritis. Whenever a new group of servicemen arrives in an endemic area, new cases occur. Almost invariably, those afflicted have had sexual intercourse, without the use of a mechanical prophylaxis, some 10 days to 3 or more weeks prior to the onset of symptoms. Although some authors hesitate to accept the venereal concept, none has expressed any doubt as to the infectious origin of the disease. Numerous organisms have thus far been incriminated—staphylococci,<sup>3</sup> diphtheroids, pleuropneumonia like organisms<sup>4</sup> and others, but no causal relationship to any has thus far been established.<sup>5,6</sup>

The absence of a predominating organism that can be cultured and retransmit the disease does not rule out a bacterial origin, but does suggest a nonbacterial origin, and a need for new culture and staining techniques. Penicillin prophylaxis has been implicated as a possible causative factor because of the rise in incidence of nongonococcal urethritis concomitant with its use. A more realistic reappraisal, however, centers attention upon the sexual indiscretion of servicemen receiving such prophylaxis. The role of alcoholism has also been discussed. It has long been known that imbibed alcohol is partially excreted in the urine and acts as an irritant, particularly in an already inflamed bladder or urethra. This is the reason for restricting its use during convalescence. Drinking is often associated with sexual exposure.

### PATHOLOGY

It is difficult to study the morbid anatomy of nonfatal diseases and one must depend upon "fortuitous" circumstances for specimens because biopsy is not indicated except under controlled research. However, one can easily observe the injection of the terminal urethra directly and the remaining urethra with panendoscopy. The frequent boggy and tenderness of the prostate is palpable and the changes in prostatic secretions observable with the laboratory microscope. The frequency of prostatic in-

involvement has been reported as 73 per cent by Ambrose and Taylor.<sup>1</sup> Our experience has been similar to theirs. For this reason we agree with Wolf and associates<sup>7</sup> who suggested that this disease is a prostatourethritis.

### THERAPY

At present therapy is empirical. Most widely employed is a combination of antimicrobial agents, dietary restrictions of alcoholic beverages, condiments and caffeine containing drinks, and often sexual restrictions. When prostatic involvement is recognized massage of the prostate is employed. We concur with the use of antimicrobials, dietary restrictions, and massage but not with complete restriction of sexual activity. During the acute phase of disease fear and anger usually restrain the patient from sexual activity, and it is only during the acute inflammatory phase that such restrictions are indicated. It is unrealistic even with the "Simon Pure" to avoid sexual stimulation and certainly the group afflicted is not Simon Pure. The resulting prostatovesicular engorgement adds to prostatic disturbances that are manageable by massage but are more completely relieved by natural means. Patients with chronic prostatic inflammation and obstruction of the prostatic acini, if married, should be encouraged to have a natural and active sexual life.

Although we employ antimicrobial agents, we know of no study of the natural history of the disease in a large series of patients. Ambrose and Taylor, in their small series of 41 cases, found that 3 patients recovered spontaneously without therapy and 3 patients had persistent discharge despite Terramycin (brand of oxytetracycline hydrochloride) therapy. Eight patients who were given placebo for six days had no demonstrable improvement; they recovered promptly after receiving Terramycin. At this hospital we have been impressed recently with the usefulness of nitrofurans as well as the tetracyclines. In a small series we have employed Furadantin (brand of nitrofurantoin) orally and Furacin (brand of nitrofurazone) as a urethral suppository with satisfactory response.

We believe that studies to evaluate various agents and to elucidate the natural history of the disease are in order. At this hospital we see few early cases, but we do eventually see almost all of the "refractory" cases in the Third Naval District from all three branches of the service. Inasmuch as new cases are generally seen first at base dispensaries and aboard ship we suggest that a study at that level would be most fruitful. Opportunity for follow up is also greatest at that level.

Our study of "refractory" cases has revealed misdiagnosis as the most common cause of therapeutic failure. The three most commonly misdiagnosed entities referred to us have been

1 Unrecognized urothral strictures These are usually congenital and are commonly at the meatus, and are easily observable but frequently not looked for. Congenital stricture at the level of the corona are common and strictures elsewhere secondary to previous infection, although fewer in number than in former years, are not rare. While the original diagnosis of nongonococcal urethritis may have been correct, cure, as with infections elsewhere, will not be accomplished until the obstruction has been relieved. For this reason all refractory cases should have the urethra calibrated and strictures discovered or ruled out.

2 Traumatic urethritis, resulting from "milking down" the urethra both to see and rid oneself of infection.

3 Venereal neuroses and guilt reactions without actual disease. The relationship of this entity to the second is evident.

Less commonly, misdiagnoses associated with the urethral discharge or other related symptomatology have been (1) urethral polyps, (2) trichomonas infections,\* (3) cancerophobia and other neuroses. Treatment for each of these entities is available and usually satisfactory.

Our opportunity for follow up is limited and statistical study is difficult because we treat a large number of men afloat and from outlying posts. We assume that a patient has been cured after therapy if he is not returned to us by a physician aboard the ship or at an outlying post who is at the same time referring to us patients with recently discovered prostatourethritis. We are certain a more careful study of so called refractory cases will reduce the incidence now estimated at 8 per cent to much lower levels.

### SUMMARY

Nonspecific prostatourethritis is a disease of unknown etiology. At present, it appears that it is infectious in origin and may be transmitted venereally, but no specific causative organism has been isolated.

Judging from the literature, the incidence is higher among the military than among the civilian population.

The therapy with which we have had the most success has included use of antimicrobial agents, prostatic massage when there is involvement of the prostate, and restriction of alcoholic beverages, condiments, and caffeine. In addition to the tetracyclines we have had satisfactory responses from using Furadantin (brand of nitrofurantoin) orally and Furacin (brand of nitrofurazone) as a urethral suppository.

The incidence of "refractoriness" will be greatly reduced if urethral strictures, traumatic urethritis, venereal neuroses, urethral polyps, trichomonas infections, and cancerophobia

and other neuroses are not misdiagnosed as being nonspecific prostatourethritis

## ANTIBIOTICS MAY BE TOXIC

Sometimes let us admit the doctor is in a panic "to do something" for a patient who has a fever while the cause of the disease has not been determined. This often results in the institution of a completely irrational regimen of antibacterial therapy. All of us should remember that any antibacterial agent may be a poison for some patients and hence use thought and discrimination in the use of sulfonamides and antibiotics. If we do this the incidence of the harmful effects of antibiotics will be lessened and the treatment of the patient and his infectious disease will be greatly improved.

# FRACTURES OF THE FEMORAL SHAFT

RICHARD M. CRONIN, *Captain, USAF (MC)*

DAVID SILVER *Captain USAF (MC)*

**T**HE increase in number of automobile accidents in the last decade, making fractures of the shaft of the femur more prevalent, and the possibility of mass casualties in this atomic age make it absolutely necessary that fractures of the femoral shaft be treated by the method which has the fewest complications and the best results. Reducing the period of disability is of particular importance to the military.

In an attempt to determine the ideal method of treatment, a study of femoral shaft fractures in regard to type of treatment, complications, and results was undertaken. The methods studied included intramedullary fixation, which has become rather widely accepted.<sup>1-3</sup> It must be utilized under the proper circumstances and has many pitfalls and complications, but some of these can be avoided.

## METHODS

One hundred and two patients with 106 fractures of the femoral shaft were either treated directly by us or were studied from case records. All of these patients were treated in United States Air Force Hospitals.

Our average follow up of patients treated by intramedullary nails was 1.7 years with a range from 2 weeks to 6 years. The average for those treated by skeletal traction suspension was 1.85 years with a range from 4 months to 5 years.

There were 95 males and 7 females. All patients were members of the armed services except two, who were female dependents. Their ages ranged from 16 to 70 years, averaging 23.4 years. Table 1 lists the causes, and table 2 the types and locations of the fractures.

These patients were treated by many different orthopedic surgeons, who used a variety of methods that have been described previously.<sup>4-7</sup> Forty seven of the patients had early intramedullary nailing and 17 had nailing plus autogenous iliac bone graft. There were 8 patients who had an open reduction with application

two groups

## RESULTS

## Intramedullary Nailing

Open medullary fixation will result in at least two groups of complications (1) Those that are related to the nail itself and (2) those that may develop as a result of an open reduction. Among the 64 patients in this series who had intramedullary nail fixation 2 had broken nails. In 1 case a new nail had to be inserted. This patient stated that since removal of the distal half of the nail through his knee he has had pain. In the other patient only the proximal half of the nail could be removed.

Another complaint in 1 patient was the migration of the nail proximally, with resultant hip pain, until it was advanced by means of a second operation. The nail could not be removed in 1 instance but fortunately was not causing any difficulty.

Hip pain seemed to be a somewhat frequent complaint and was noted in 29 per cent of those with intramedullary nail fixation. It was usually caused by bursitis and inflammation in the region of the proximal tip of the extruding nail. Often the bursa would become calcified, leading to increased pain. The pain was noticed particularly after the patient had been sitting for varying periods of time.

In this series there were no complications as a result of the length or diameter of the nail, such as sometimes occurs.<sup>10</sup> There were no instances of the nail cutting out or splitting the femoral shaft. The problem of a nail being stuck at the isthmus of the femoral shaft was not encountered. Fat emboli and surgical shock were not encountered in this series. Two patients developed cardiac arrest, one responded to cardiac massage and the other died. Cardiac arrest took place before the incision was made in one of these patients. Two instances of osteomyelitis were recorded, one of which was in the shaft in a closed, comminuted fracture and the other at the site of an iliac bone graft. There were two cases of pulmonary embolism and one each of phlebotrombosis and thrombophlebitis. None of these four were fatal. One patient developed a nonunion because the intramedullary nail had migrated proximally. There were two cases of malunion. One occurred because the nail had bent, resulting in an anterior and lateral bowing of the shaft. In the other, an external rotation deformity below the fracture site required a later osteotomy.

Shortening was present in 19 per cent of those treated by intramedullary nailing. Eighteen per cent stated that they either had pain of some degree or some loss of motion in the knee.

#### Skeletal Traction

In the 25 patients treated with skeletal traction and suspension, there were 5 instances of malunion and 1 of nonunion. The pin tract in the tibia became infected in 1 patient with a resultant osteomyelitis. One patient developed a thrombophlebitis and another cystitis with calculus formation in the ureter. Forty-eight per cent claimed to have some difficulty with their knee, either pain or loss of motion, while 60 per cent had some degree of shortening. Table 3 compares the incidence of certain complications in patients treated with intramedullary nailing with that of patients treated with skeletal traction.

TABLE 3 *Comparison of incidence of complications in intramedullary nailing with the incidence in skeletal traction*

Complication	Method of treating fracture	
	Intramedullary nail (per cent)	Skeletal traction (per cent)
Bone		
Malunion	3.1	20
Nonunion	1.6	4
Refracture	1.6	8
Shortening	19	60
Osteomyelitis of tibial pin tract		4
Joint		
Pain or loss of motion in knee	18	49
hip	29	28
Prolonged bed rest		
Thrombophlebitis	3.1	
Pulmonary embolism	3.1	
Cystitis and ureteral calculus		4

#### Open Reduction and Fixation With Metallic Plate and Screws

Complications in the eight patients treated with this method included one instance each of osteomyelitis, a broken plate with refracture and delayed union. One patient had a tremendous blood loss following surgical procedure that required a transfusion of 5 000 ml. of blood.

#### Manipulation and Plaster Immobilization

Any analysis of this method might be misleading, for there were only four patients in the group. These four tended to have difficulty regaining knee motion, and three of them had some shortening.

#### Complications of the Fracture Itself

There were two supracondylar amputations in our series. Both of these were a result of direct vascular injury to the femoral artery. One was a closed comminuted middle third fracture, while the other was an open comminuted fracture at the junction of the middle and distal thirds. In one patient the artery was lacerated in the adductor canal while in the other it was lacerated in the popliteal area just after leaving the canal.

#### Return To Duty

In the military service a patient is not returned to duty until he is capable of performing his job. Thus, the hospitalization

is normally longer than in civilian life where the patient can convalesce at home before returning to work. We found that the average time for 102 patients before returning to full military duty, using all methods of treatment, was 4.7 months. The time for the patients with intramedullary nails was 3.2 months, with a range from 1 to 7 months. The average time for skeletal traction suspension method was 6.9 months, with a range of from 3 to 15 months. The number of patients treated with the other methods was too small to analyze, but none of them returned to duty as early as the group treated with intramedullary nails.

### COMMENTS

Fractures of the femur are very serious injuries, and the results of the treatment often leave much to be desired. Many of the complications that result from nailing can be overcome if proper conditions are satisfied. First, the fracture must be in the middle three fifths of the shaft. Secondly, the patient should be an adult in good general condition. Inasmuch as a fracture of the shaft of the femur requires a tremendous force, other associated injuries are often present. We found a rather high incidence of associated cerebral concussions. It is mandatory to wait until there are absolutely no contraindications to surgical intervention. Shock and blood loss should be vigorously treated before the patient is operated on. A patient with a femoral fracture treated by intramedullary nail fixation who suffers severe shock on the operating table obviously would have been better treated by skeletal traction. The nailing of open fractures should be postponed until the skin has healed and there is no evidence of infection. An osteomyelitis of the femur is a discouraging complication. There was only one case of osteomyelitis of the femur and one of the iliac crest in this series. It is absolutely necessary that the nailing be performed by a skilled bone surgeon. There should be adequate assistance, supervision, good instruments, and most favorable operating room facilities.

If the above conditions are fulfilled, intramedullary nailing of the fractured femoral shaft seems to be the best method of treatment. One of the most significant advantages is that less time elapses before return to duty. In our series, the patients treated with intramedullary nailing returned to duty almost four months sooner than those treated with the skeletal traction and suspension method.

Brav and Jeffress<sup>11,12</sup> thoroughly reviewed the healing time of these fractures and found it to average 16 weeks. Patients treated with the traction and suspension method did not heal any faster in our series. It is important to remember that the patient treated by nailing may be ambulatory while his fracture is healing.<sup>13-16</sup>

## SUMMARY

From a statistical study of 106 fractures of the femoral shaft it was found that patients returned to duty 3 7 months sooner with intramedullary nail fixation than with the skeletal traction suspension method Intramedullary fixation offered the best method of treatment of these fractures

# ELECTROMYOGRAPHY

## Value in a Military Hospital

BENJAMIN L. CRUE Jr. *Lieutenant Commander MC USN*

THE CLINICAL value of electromyography, using a cathode ray oscilloscope with adequate shielding and with needle electrodes, has already been adequately documented<sup>1-3</sup> In recent years, this technic has been increasingly used in certain sections of this country by physicians, the majority of whom are specialists in the field of physical medicine During the year 1955-1956, the author carried out 186 electromyographic examinations at this hospital Inasmuch as the average time required for each examination was about 20 minutes, this represented over 60 hours spent in 1 year doing this one type of diagnostic test while at the same time running a busy neurosurgical ward This study was made to determine whether such an expenditure of time and effort was justified

### METHOD

Electromyographic examinations were performed, when indicated, both on outpatients in the neurosurgical clinic and on inpatients Some patients were referred from the neurologic and orthopedic services especially for this test Inasmuch as there was little teaching involved and little reason to believe that many of the cases would come to litigation, photographic tracings and magnetic tape recordings were seldom made Instead, the results were reported directly

### RESULTS

Of the 186 electromyograms performed,\* 125 (67 per cent) were positive and only 61 (33 per cent) were negative Of these 125 positive electromyograms, 66 were caused by lumbar "discs," 7 by cervical disks, 29 by peripheral nerve injuries, and 23 by such interesting diseases as Friedreich's ataxia (Roussy-Lévy syndrome), syringomyelia, myasthenia, cord tumor (neurofibroma),

These examinations were made with the Meditron electromyograph model 201A (fig 1)

progressive spinal muscular atrophy (including amyotrophic lateral sclerosis), multiple sclerosis myotonia poliomyelitis, and several cases of lower motor neuron neuritis of unknown cause (Guillain Barre syndrome)

Figure 1 The Meditron electromyograph and sample tracings (A) Calibration, 60-cycle voltage 200 microvolts per inch sensitivity (B) Electromyographic silence of normal muscle (C) Normal motor unit voltage voluntary (D) Denervation fibrillation voltage involuntary (E) Complex (polyphasic) motor unit voluntary (F) Myotonia. (Pictures and captions adapted from Meditron chart)

An effort was made to compare the diagnostic accuracy of electromyography to myelography in the lumbar disk syndrome. In a previous series of 136 consecutive cases of proven L4-L5

and L5 S1 disks, the myelogram was found to be slightly superior in detecting a L4 L5 disk, while the electromyogram was more accurate with a L5 S1 disk. Only one error in preoperative localization was made—an accuracy of 99.4 per cent<sup>4</sup> (Electromyograms performed by Dr. James Golseth).

In the present series there were 31 patients on whom both electromyograms and myelograms were done and who were proved by laminectomy to have herniated disks (table 1). In these 31 cases where the accuracy of localization could be compared, the myelogram was the most accurate (81 per cent), the electromyogram next (74 per cent), and clinical localization last (68 per cent). The clinical localization of the herniated disk was based on motor (S1 root, decreased ankle jerk, L5 root, weakness of dorsiflexion of foot) and sensory signs (S1 root, lateral foot, L5 root, dorsum of foot). Clinical signs are thus root signs and subject to the same error of interpretation of level as the electromyogram. Thus, a midline L4 L5 disk affecting the S1 root would be interpreted as an L5 S1 disk both clinically and by the electromyogram. Every leniency was allowed in considering a myelogram as being indicative of a herniated disk. Several of the positive myelograms were small asymmetries "consistent with but not diagnostic of a herniated disk."

TABLE 1 Comparison between accuracy of clinical judgment, electromyogram, and myelogram in locating herniated "disks" in 31 patients

Location of "disk" at operation	Number of patients	Results			
		All three methods correct	Erroneous results*		
			Clinically	Electromyogram	Myelogram
L3 L4	1	1	0	0	0
L4 L5	9	4	2	3	3
L5 S1	19	9	5	3	2
L4 L5 + L5 S1	2	0	2	1	0
Total	31	14	9	7	5

\*In only 3 patients was more than one test either negative or in error.

It should be noted that although a definite indication of a defect on myelography, if it fitted the clinical picture, usually resulted in laminectomy, there were a number of patients with a less severe clinical syndrome who had minimal electromyographic findings of root compression, and did not have a laminectomy.

There were 21 errors out of 93 possible chances (3 tests on each of the 31 patients) In only 2 patients was there an error in preoperative localization of the lesion when all three factors were evaluated One was the previously mentioned midline L4 L5 disk giving both the clinical and electromyogram picture of an S1 root lesion This was interpreted as a probable L5 S1 disk, and myelography failed to disclose the error, as there was a congenitally anomalous dural sac ending at the L5 level The second case in error was a patient who had had two previous laminectomies Clinically only an unstable back was diagnosed, and the electromyogram was negative Myelography was compatible only with postoperative scarring, but on routine exploration before a spinal fusion a recurrent L4 L5 extrusion was found

### Peripheral Nerve Injuries

Even in peacetime a military hospital still receives a large number of patients with peripheral nerve injuries of a wide variety Included in this series were ulnar nerve lesions from elbow trauma and from lacerations of the wrist radial nerve lesions from Saturday night paralysis and from fractures of the humerus median nerve injuries incurred in automobile accidents and several brachial plexus injuries caused by severe trauma There were several cases of partial paraplegia following fracture of the spine at the caudal level where electromyography helped in ascertaining the root injury level One boy had fractures of all the transverse processes in the lumbar area on one side He had no abnormality of the lower motor neuron of the anterior primary division but apparently there was almost complete denervation of the posterior primary divisions in the lumbar area There were sciatic nerve injuries and several peroneal injuries producing foot drop some of which were difficult to distinguish from lumbar disk injuries or poliomyelitis The value of electromyography in following the regeneration of peripheral nerve injuries is well known and will not be discussed in detail here There were two cases however where the diagnosis of a nerve injury in continuity could be made and unnecessary operations prevented even though there was no grossly visible movement because the electromyogram showed the presence of functioning voluntary motor units Both patients recovered on conservative management

### CASE REPORTS

There were several unusual cases that show the value of electromyography

**Case 1** A 41 year old sailor had been admitted complaining of weakness of dorsiflexion of the left foot and minimal back pain The dif

cytes. An electromyogram showed no abnormalities but it was my impression that this probably was a case of poliomyelitis. The patient was admitted to the hospital and placed on bed rest. During the third week after the onset of weakness he developed definite denervation fibrillation in the already recovering right lower extremity. He made a prompt clinical recovery and returned to his class at the Academy.

Cases 3 and 4. Two patients were suspected clinically of having a herniated nucleus pulposus in the lumbar region and were referred for possible myelography. The electromyogram showed widespread lower motor neuron disease. Both patients subsequently were shown to have an infectious neuritis.

Case 5. Another unusual case was encountered when a young sailor was referred with the diagnosis of a left sixth cranial nerve lesion. He was scheduled for a "squint" operation on his left external rectus muscle. The ophthalmologist demonstrated that he could not follow laterally beyond the midline with his left eye. An electromyogram of his left lateral rectus was entirely negative, showing no denervation fibrillation when the muscle was inhibited by having him look to the right. This was a disappointment to the examiner as well as the ophthalmologist. It was interpreted as a failure of technique. Only later was it discovered that the patient must have had a very unusual unilateral supranuclear lesion. While he could not follow objects laterally with his left eye, he could externally rotate his left orbit to command.

Case 6. There is still much to be learned about the clinical use of this diagnostic tool in various pathologic conditions. Multiple sclerosis is usually considered a disease affecting primarily the white matter of the central nervous system. However, the nerve roots may show pathologic change. Electromyography on several patients with multiple sclerosis who had weakness in the lower extremities revealed only uncontrollable bursts of voluntary motor units characteristic of upper motor neuron disease but no evidence of lower motor neuron disease. However, in a recent case which has now progressed so that we are relatively certain of the clinical diagnosis of multiple sclerosis, the patient had in her lower extremities widespread complex motor units of a very marked degree without any real denervation fibrillation of fasciculation. This is possibly an example of the concept of demyelination without Wallerian degeneration. Whether one can interpret this type of finding in a demyelinating disease such as multiple sclerosis remains to be proved.

## DISCUSSION

### Technic of Examination

The electromyographic examination should be carried out by a physician who is familiar with the technic, who has some knowledge of the neuroanatomy and the suspected neurologic syn-

June 1957)

drome involved, and who has at hand at least a brief history of the individual patient's problem

It is not believed that a technician or medical corpsman could be trained to do this type of examination adequately by himself, although under proper supervision such trained personnel would be of great assistance

Performing electromyography on one's own patients has at least three advantages. First, there is the ability to choose which patients should be so examined. Second, there is an excellent opportunity in many cases to obtain prompt follow up correlations. For example, an electromyogram and a myelogram are often done one day, and a laminectomy is performed the following morning. Third, the examiner knows exactly what is wanted and can shorten the procedure, yet include pertinent parts of the examination. For example, if I know from taking a history and doing a physical examination, that a patient has low back pain with definite sciatic radiation and weakness of dorsiflexion of the great toe, all I want to know from the electromyogram is whether there is any denervation fibrillation in the distribution of the L5 nerve root as compared to the area supplied by the L4 and S1 roots. Consequently, only three muscles are tested: the quadriceps (L2-3-4), the anterior tibial (L4-L5), and the gastrocnemius (S1-2). The hamstrings, the gluteus, or the posterior primary divisions would not be tested.

The report in the record is mainly for my own evaluation and I usually need not worry whether another physician can interpret the recorded findings. While this type of examination destroys the strictly scientific objectivity of the test, the time saved is considerable and permits an over all average of about 20 minutes per examination. It further saves the patient needless needle punctures and allows a more thorough search to be made in the area of a clinically suspected abnormality. Of course, this abbreviated type of examination can only be used in certain selected cases.

#### Military vs Civilian Use

One difference between neurosurgical practice in a military hospital as compared to a large civilian neurosurgical center is the relatively larger preponderance of low back disorders and cases of peripheral nerve injury found in the service, even in peacetime. This should be reflected in a larger percentage of military neurosurgical patients who would be candidates for an electromyographic examination. In this series, however, electromyograms frequently were not done on patients with obvious peripheral nerve lesions, nor were they done on all patients with back disorders. This was only because of lack of time and be-

cause no other physician trained in electromyography was available

An example of the difference in the type of patients examined is shown in the percentage of positive electromyograms. Of the 186 electromyograms performed 125 (67 per cent) were positive and only 61 (33 per cent) were negative. In a civilian electrodiagnostic clinic, where patients are referred for various reasons by many different doctors, negative examinations are in the majority. Such a large percentage of positive electromyograms did not result from my eagerness to find denervation fibrillation. It was produced by selectively choosing the patients on whom electromyography was done.

Although there may be a significant number of false negatives in electromyography, one of the advantages of the test is that there should be no false positives although there may be incorrect interpretation of the findings. In all suspected root compression syndromes a positive record is not reported unless denervation fibrillation (fig 1) is definitely present. The large majority of patients who are examined for low back disorders are from the neurosurgical service. A certain number of these patients however are referred from the neurologic, orthopedic and even from the psychiatric services, where a negative electromyogram is expected but is desired as part of the clinical study.

One of the main values of electromyography is in the detection of early minimal root compression. This is not as true in military medicine as in civilian practice where disability litigation may be involved. Although the military patient either has to be fit for duty or remain hospitalized until disposition is made, negative evidence as for an industrial compensation board need not be gathered.

Each patient with a low back disorder was judged clinically as to whether or not he had herniated disk. Patients with mechanical disorders of the back were transferred to the orthopedic service. A patient was referred for either electromyography or myelography only if he was suspected of having a "disk" and was having enough pain so that if the electromyogram and the myelogram were positive laminectomy would follow. There was not time to do electromyograms on those patients who had minimal complaints and who would not have been advised to have an operation even if the electromyogram did lend further substantiation to the clinical diagnosis of minimal root compression. These patients were all treated conservatively and a large majority of them returned to duty without having either an electromyogram

or a myelogram. In a number of cases in which the diagnosis was questionable, an electromyogram was done even though the complaints might have been minimal. These patients made up a large share of the negative reports.

#### Comparison of Electromyogram With Myelogram

In the comparison of electromyogram to myelogram, the relative value is not shown in its true aspect. The 7 electromyographic errors included 2 where the test was done before the necessary 3 weeks had elapsed since root compression. This error was kept to a minimum by usually not doing electromyograms on patients without a history of at least 21 days of sciatic pain. One other case was an error in localization where an L4 L5 midline disk affecting the S1 root had been interpreted as an L5 S1 disk. The other 4 errors were in missed diagnoses, that is, the electromyogram was negative although a definite herniation was found at operation. The nerve roots unfortunately were not stimulated to see whether there had been damage to the conductivity of the motor efferent fibers. It is thought that it is possible to have a disk protrusion doing enough damage to the roots to cause considerable pain (and give a large myelographic defect) without much motor damage, resulting in a normal electromyogram. However, in 2 of the 4 cases with normal electromyograms there had been nerve root damage of long standing with considerable atrophy, weakness, and reflex change. A normal electromyogram in this situation is not completely understandable unless the author's method of trying to sample 40 different areas in one muscle tested is not statistically adequate. Basically, however, electromyography is of comparable accuracy to myelography for diagnosing herniated lumbar disks. It is certainly an easier preliminary screening test and there was at least 1 case in the 31 where the patient would not have had a myelogram or an operation had the electromyogram not been found to be positive. It was believed that the patient had a functional, stocking anesthetic, but after repeated returns to the clinic an electromyogram was done in desperation and to our surprise showed considerable fibrillation in the distribution of the S1 root. I feel certain that in this case much additional time would have elapsed before any neurosurgeon would have contemplated performing a myelogram on the patient, in view of her particular history and complaints.

#### SUMMARY AND CONCLUSIONS

During the year 1955-1956, 186 electromyographic examinations were carried out on the neurosurgical service of this hospital. Of these, 125 (67 per cent) were positive.

In a series of 31 consecutive cases of herniated lumbar "disk" proved by laminectomy the electromyogram was correct in 74 per cent of the cases the myelogram in 81 per cent. By combining the results only 2 errors in preoperative diagnosis of location were made.

Several unusual cases in which the electromyogram was of especial help or interest are presented briefly.

The advantages of electromyographic examination of patients with whom the examiner is familiar is stressed.

It is concluded that electromyography is of definite value in a military hospital. Although the cases described in this report emphasize particularly the value of electromyography in the diagnosis of herniated intervertebral disks it also is useful in peripheral nerve injuries and other neurologic and neurosurgical conditions.

# NONSPECIFIC EPIDIDYMITIS IN THE MILITARY SERVICE

WILLIAM M. ROSS *Major MC USAR*  
JAMES H. MAYNARD *Captain MC USAR*

**N**ONTUBERCULAR, nongonococcal epididymitis is far more common than textbooks would lead one to believe, and the incidence in military personnel is particularly high. Military surgeons have often observed this condition in men who are otherwise entirely well but have been forced to march or parade for long periods of time, or have been subjected to marked exertion, but who have had no instrumentation or operation. These cases occur frequently enough to account for a significant number of hospital admissions to the urologic service of the average Army hospital, and result in many duty hours lost. In 1956, Gartman<sup>1</sup> reported that of 189 patients with epididymitis, there were 76 acute and 14 chronic cases of which the cause was not known, although retrograde flow of urine was considered.

Numerous cases of nonspecific epididymitis have also been reported in industry. Amdur,<sup>2</sup> in 1943, described 14 industrial cases, most of which occurred after muscular exertion. Many of the patients admitted a full bladder at the time of strain. These cases were characterized by an absence of constitutional symptoms, urinary symptoms, or urethral discharge. Urine examination was essentially negative in all of the patients. It was suggested that the clinical picture could be explained as an irritant response to the retrograde propulsion of urine down the vas deferens.

Anatomically, this theory seems entirely plausible. The prostatic urethra is the widest portion of the urethra, its proximal end being closed by the internal sphincter and its distal end by the membranous urethra, which is the narrowest and most rigid portion of the canal. At the time of strain, urine may pass through the internal sphincter and be blocked at the external sphincter, some of the urine being forced into the ejaculatory duct and down the vas deferens. This would be most likely to happen with a full bladder.

It has been shown experimentally that urine can be made to travel in this retrograde manner.<sup>3-5</sup> Graves and Engal<sup>4</sup> injected

fluid down the vas deferens in dogs, using sterile urine obtained from the animal on one side and saline on the other side for control. The saline injection did no harm but inflammation of the epididymis developed on the side injected with urine. These investigators proposed the concept that sterile urine can find its way into the vas deferens and cause a chemical epididymitis.

Our study was undertaken to better understand the nature of acute idiopathic epididymitis particularly as it applies to the military. Ninety-two cases of epididymitis of which 90 were nonspecific, were observed over a 15 month period at this hospital. A large number of this group of patients were trainees. The age range was 17 to 37 most of the patients being from 19 to 22 years of age. In each case a careful history was taken and a complete physical examination made. The following laboratory procedures were performed in each case: total and differential leukocyte counts, complete urinalysis, urine culture and examination of a smear of the prostatic secretion.

These patients were first seen from 12 hours to 5 days after the onset of symptoms, the majority being seen within 24 to 48 hours. The onset in 32 patients was described as sudden, with severe scrotal and inguinal pain, followed in a few hours by scrotal swelling. In the remaining 60 patients the onset was slow with symptoms reaching their height in 24 to 48 hours. Of the total number of patients, 16 (less than 20 per cent) complained of constitutional symptoms such as malaise, headache or loss of appetite. The others did not feel nor appear ill. Twenty-one of the patients showed a temperature elevation over 99.5 F, 8 of these having a temperature of over 100 F. The highest temperature was 102 F.

Symptoms of epididymitis (table 1) appeared after physical training in 12 patients, after heavy lifting in 16, after long marches in 13, and after a long automobile ride in 2. Twenty-one of the patients reported that they felt an urgent need to urinate at the time of exertion or marching.

TABLE 1 Symptoms of 92 patients with epididymitis

Symptom	Number of patients
Scrotal pain	92
Scrotal swelling	92
Urinary symptoms	18
Urethral discharge	2
Fever	21
Malaise	2

Of the 92 cases studied, 5 were recurrent. Seven patients gave a positive history of gonorrhea, each apparently having been cured with antibiotics. A minimum of four months had elapsed from the time of gonorrheal infection until the attack of epididymitis occurred. Urinary symptoms such as frequency, burning, and dysuria were reported by 18 patients. No patient gave a history of hematuria. One patient had a slight urethral discharge at the time symptoms of epididymitis developed, which was negative for gonorrhea. Another patient had a discharge that was positive for gonorrhea two days prior to the onset of the symptoms of epididymitis.

Of the 92 cases of epididymitis, 52 were on the left side, 39 were on the right, and 1 was bilateral. Examination revealed a moderate to marked enlargement of the whole epididymis in 88 patients, the lower pole alone being enlarged in 4. The epididymis was very hard and tender in all cases. The prostate was considered to be abnormal in 10 patients—enlarged and boggy in 4 of these, indurated and irregular in 5, and definitely enlarged, hard, and markedly irregular in 1, this last case being proved to be caused by tuberculosis.

The white blood cell count was elevated in 24 cases. Of these, the highest count was 20,000 per  $\mu$ l, most patients in this group having counts between 12,000 and 14,000 per  $\mu$ l. The count in the remaining 68 patients was under 10,000 per  $\mu$ l. Urinalysis was reported as negative in all but 26 cases, and most of the positive urines contained only a few pus cells. Prostatic secretions of 11 patients were considered abnormal, with a marked increase in the number of white cells in 2 cases. Urine culture was positive in 13 patients—*Escherichia coli* in 11, *Micrococcus pyogenes* var. *albus* in 1, and *Mycobacterium tuberculosis* in 1.

#### TREATMENT AND RESULTS

All patients were treated with a firm scrotal support, ice bag, and bed rest, followed in a few days by gradually increased activity with a support. In the late stages, heat in the form of Sitz baths was employed. It has been our impression that the use of cold in the early stages, rather than heat, is more effective in making the patient comfortable and in bringing about rapid resolution. Sixty of the 92 patients were given penicillin, aureomycin, terramycin, or streptomycin, alone or in combination. The remaining 32 patients received no antibiotics.

Most of the patients were quite comfortable after the first 24 hours of hospitalization, and only a few required more than aspirin for the relief of pain. The length of hospital stay varied from 5 to 45 days, the majority returning to duty in 14 to 18 days (table 2). Antibiotics were of value in treating the patients with urinary infection, abnormal prostatic secretion, or constitutional symptoms. The course of events in t

TABLE 2 Length of hospital stay of 92 patients with epididymitis

17 25	29
26 35	12
36 45	4

influenced little or not at all by antibiotic. Of the 92 patients treated, 6 had recurrences. In one patient the inflammation persisted in spite of antibiotics, showed definite evidence of suppuration and necessitated eventual orchiectomy. Orchiectomy was also performed on the one patient with tuberculous epididymitis. The disease became chronic in four patients and was treated by epididymectomy. There was no evidence of suppuration in the majority of patients. The patients were followed for periods of from 1 to 6 months after release from the hospital. Follow up examination revealed the presence of a small residual nodule in the lower pole of the epididymis in 86 patients. In the other 26 patients resolution appeared to be complete. Atrophy of the testis was not observed.

#### CONCLUSIONS AND SUMMARY

The occurrence of acute epididymitis is a relatively common occurrence among young military personnel, the vast majority of these cases being classified as nonspecific. In the present series of 92 cases, only 2 were found to be specific (1 caused by tuberculosis and 1 by gonorrhea). Of the nonspecific cases most appeared to be abacterial as evidenced by the laboratory findings and the lack of constitutional and urinary symptoms. Suppuration also was notably lacking. Those findings though not conclusive, lend support to the mechanicochemical theory in the production of the majority of these cases. In those cases that we have classified as abacterial the use of antibiotics appeared to be of questionable value.

Strain and exertion often play a part in the production of epididymitis, and this is especially likely to happen when the bladder is full. Emptying the bladder prior to strenuous exercise or long marches may possibly be of value in decreasing the incidence of acute epididymitis.

In only an occasional patient with nonspecific epididymitis was surgical intervention necessary. Operative treatment is advisable in chronic symptomatic epididymitis and in stubborn recurrences. Epididymectomy is preferred over orchiectomy as the operative procedure.

## SERVICEMEN AND MOTOR VEHICLES

Service personnel have one of the worst accident records of any group in the nation. Automobiles driven by young servicemen are "an undesirable insurance risk." Military personnel are involved in about one out of every 30 fatal accidents in the United States! Yet servicemen and women don't add up to nearly 1/30 of the total population—nor do they drive even one out of each 30 miles driven in the nation.

While motor vehicle accidents are the major cause of off duty deaths and injuries in the armed forces, other types of accidents also account for a considerable number of off duty casualties each year. Off duty accidents are the most important accident problem facing the armed forces. Strangely enough, these mishaps befall the same men and women who—day after day—cope successfully with far greater risks while on their jobs.

The terrific cost of injuries and fatalities in armed forces personnel cannot be measured accurately in dollars and cents. Merely taking the \$10,000 Government life insurance policy which was paid to the beneficiaries of the 3,657 accidental deaths in the armed forces during 1953 contributed the sum of \$36,570,000 to the total cost of these accidents.

# COURSE ON EMERGENCY MANAGEMENT OF THE NATIONAL ECONOMY

The Industrial College of the Armed Forces operates under the direct supervision of the Joint Chiefs of Staff and is charged with bringing the problems and methods entailed in maintaining national economic readiness to the attention of Regular, Reserve and National Guard officers and civilians and Government personnel who may hold positions of importance to the national economy in an emergency. The College conducts resident and extension courses, and a series of National Resources Conferences.

**Extension Course.** A correspondence course on Emergency Management of the National Economy is designed to educate civilian and military key personnel who cannot attend the Resident Course, in regard to the all important civilian military relationship upon which the Nation depends in this era of constant readiness. The two are inseparable and there must be the highest degree of co-operation and understanding.

Immediate benefits accrue to enrollees. The graduates of this unique course are better informed and therefore more capable of understanding the significance of national and international happenings. The textbooks and examinations explain the interdependence and relationship of the many subject areas that have an important bearing on economic readiness.

A certification of completion is awarded by the Industrial College of the Armed Forces to every student who successfully completes the course, and the military services have authorized the award of 48 credit points for retention, promotion and retirement to Reservists not on active duty. All graduates may retain the textbooks which are available through no other source and constitute a valuable addition to the personal library of anyone concerned with the future of the military, the Nation's economy and the world situation as it affects our plans and policies.

Those who wish to enroll in the extension course may communicate directly with the Correspondence Study Branch, Industrial College of the Armed Forces, Washington 25, D. C. A prospectus will be forwarded which outlines the eligibility requirements and includes an application form and necessary instructions.

Patients who have an early rupture of the membranes or a firm, long, and undilated cervix will benefit most from early cesarean section.<sup>11</sup> This is the preferred method of treatment in patients with transverse presentation associated with a live baby unless the cervix is at full dilatation, and one can accomplish internal version easily.<sup>1</sup> Requirements for internal version and extraction include a sound uterus, complete cervical dilatation, no disproportion, and a sufficient quantity of amniotic fluid.<sup>1</sup> Following vaginal delivery, the uterine walls should be manually explored to rule out the possibility of a ruptured uterus.<sup>1</sup> The use of antibiotics, oxygen, and blood, when indicated, are helpful adjuvants to the management of the mother and child.

**Complications.** In more recent times, maternal deaths from transverse presentation have been uncommon but the morbidity continues to be high. Puerperal infection and hemorrhage have been the leading factors. The major causes of hemorrhage in this condition are placenta previa, abruptio placenta, uterine rupture, and cervical lacerations. Internal version and extraction is not a benign procedure. In 1945, Morrison and Douglass<sup>12</sup> noted that internal version and extraction was second only to previous cesarean section as a cause of ruptured uterus. The fetal mortality is particularly high in vaginal delivery and increases in direct proportion to the duration of labor.<sup>1</sup> Causative factors in fetal mortality include prolapsed cord, anoxia due to uterine tetany, and birth trauma.<sup>1</sup>

#### EXPERIENCE AT THIS HOSPITAL

During 1954 and 1955, there have been 5 cases of transverse presentation among 2,116 deliveries at this hospital, an incidence of 1 in 423 deliveries. Although we realize that no conclusions can be drawn from this small series, we are reporting our findings. The patients were all in labor at the time of diagnosis, after gestation periods of 29, 30, 36, 36, and 40 weeks, respectively. Possible causative factors for the transverse presentation included a low implantation of the placenta and multiparity associated with a relaxed abdomen in one patient, and a moderate degree of hydramnios in two patients. The causes in the other two patients were unknown. Four of the patients were delivered by cesarean section and one by internal version and extraction. The latter was in her 29th week of gestation. The four babies delivered by cesarean section are living, the one delivered by internal version and extraction died at one month of age from complications associated with prematurity.

#### SUMMARY

Although the incidence of transverse presentation of the fetus is relatively low, the associated fetal mortality and maternal morbidity are still impressively high.

a greater degree of fetal mobility Other important causative factors include hydramnios, fetal death in utero, ventral hernia, pelvic tumors, full bladder or rectum, bicornate uterus, pre mature labor and a contracted pelvis

**Diagnosis** Inspection of the abdomen alone is often enough to arouse suspicion that a transverse presentation exists because the fundus of the uterus lies at a lower plane than usual and the abdominal enlargement is transverse to the mother's longitudinal axis The head and breech can be ballotted in the iliac fossae Examination rectally or vaginally may reveal the absence of fetal parts, or there may be a prolapsed extremity, shoulder cord, or thorax presenting Roentgenography confirms the position of the fetal skeleton, and soft tissue technics and cystograms aid in locating the placenta All patients who are suspected of having a footling breech and those in whom the diagnosis of a breech is uncertain, should have vaginal and roentgenographic examinations to rule out transverse presentation

**Treatment** Transverso presentation is a diagnosis which should be made during one of the prenatal visits After the diagnosis has been made, an attempt should be made to find the causative factor and locate the placenta, through the use of physical and roentgenographic examinations External version should be attempted when the condition is diagnosed, unless placenta previa uterine bleeding a dead fetus, or hydramnios are present, or when elective cesarean section is planned for some other reason, or when labor has progressed too far at the time of diagnosis

The dangers of doing external version are minimal if certain precautions are followed In order to prevent the placenta from being damaged the part of the uterus that houses the placenta should not be handled The patient should be prepared by having her bladder emptied Pillows should be placed under her head shoulders and knees in order to encourage good relaxation of her abdomen Talcum powder may be applied to the flat of one's hand steady gentle manual pressure is applied to the fetal pole After version is accomplished the fetal heart tones should again be auscultated and if they are abnormal the procedure for version must be reversed The patient should be checked weekly after the 32d week and external version repeated, if necessary External version may be attempted even when the diagnosis is made in early labor Spontaneous version to the cephalic presentation occurs in about 27 per cent of the cases

# ARTIFICIAL RESPIRATION TECHNIC FOR INFANTS AND SMALL CHILDREN

*At the request of the American National Red Cross, the National Academy of Sciences—National Research Council convened an Ad Hoc Panel on Manual Methods of Artificial Respiration on 8 March 1957 to advise as to the best method presently available for administering artificial respiration to infants and small children. The panel, comprising many eminent authorities on the subject, unanimously recommended the technic herein described*

—Editor

## TECHNIC FOR ADMINISTRATION

### *Step 1*

Clear the mouth of any foreign matter with the middle finger of one hand. With the same finger hold the tongue forward (fig. 1)

### *Step 2*

Now place the child in a face down, head down position and pat him firmly on the back with the free hand. This should help dislodge any foreign object in the air passage (fig. 2)

### *Step 3*

Place the child on his back and use the middle fingers of both hands to lift the lower jaw from beneath and behind so that it "juts out" (fig. 3)

### *Step 4*

Hold the jaw in the position described in Step 3, using one hand only (fig. 4)

### *Step 5*

Place your mouth over the child's mouth and nose, making a relatively leakproof seal, and breathe into the child with a smooth steady action until you observe the chest to rise. As you start this action, move your free hand to the child's abdomen, between the navel and the ribs, and apply continuous moderate pressure to prevent the stomach from becoming filled with air (fig. 5)

### *Step 6*

When the lungs have been inflated, remove your lips from the child's mouth and nose and allow the lungs to empty. Repeat this cycle, keeping one hand beneath the jaw and the other hand pressing on the stomach at all times. Continue at a rate of about

The factors operative in producing transverse position of the fetus include polar implantation of the placenta multiparity hydramnios, fetal death in utero, ventral hernia pelvic tumors full bladder or rectum, bicornate uterus, premature labor, and a contracted maternal pelvis

Abdominal or rectal examination usually discloses the transverse position Roentgenography will confirm the position of the fetal skeleton and the placenta may be located by using soft tissue technic

Transverse presentation is treated by either cesarean section or version External version may be attempted unless placenta previa, uterine bleeding a dead fetus or hydramnios are present or labor has progressed too far at the time diagnosis is made Cesarean section is the preferred method of treatment in patients with a live fetus who are in labor, unless the cervix is fully or almost fully dilated at the time of diagnosis, or internal version may be easily accomplished

During the two years 1954 and 1955 five patients with transverse presentation have been treated at this hospital Four of these were delivered by cesarean section and the infants survived One was delivered by internal version after 29 weeks of gestation the infant dying one month later from complications of prematurity

# ARTIFICIAL RESPIRATION

20 cycles per minute After every 20 cycles you should rest long enough to take one deep breath If at any time you feel resistance to your breathing into the child and the chest does not rise repeat Step 2, then quickly resume mouth to-mouth breathing

### USE FOR INJURED ADULTS

The question often arises concerning a technic to use on adults when the chest cage is injured and compression of the chest would do further damage, or when fractured upper extremities would eliminate the expansion phase of "push pull" technics The mouth to-mouth or mouth to-nose technic may be used in these cases however, the cycle should be slower than that used for children Approximately 12 cycles per minute should be adequate The lower jaw must be held in the "jutting out" position with both hands at all times

---

## Clinicopathologic Conference

U S Naval Hospital Portsmouth, Va •

### CARDIAC ARRHYTHMIA

**Summary of Clinical History** The patient was 33 years old when, on 26 November 1956, he was admitted to a hospital for the first time in his life. During examination for extension of enlistment after 10 years of active duty in the U S Navy, it had been noted that his pulse was markedly irregular. He was not conscious of any irregularity and had no complaints of any sort. He had had the usual childhood diseases, none of them serious, and at the age of nine had had pneumonia without any sequelae. He remembered no operations, accidents, or any other serious illnesses. Particularly, there was no history of rheumatic fever. His mother and father had died of unknown causes while he was an infant. Two siblings were alive and well.

During his 10 years in the Navy, he had been in the Philippines, Alaska, South America, United States, Mediterranean, Greenland, South America, and the United States, in that order. He drank about two bottles of beer a day and occasionally used hard liquor. For some years he had smoked one and a half packages of cigarettes per day.

On review of systems, the only positive finding was that the patient occasionally had abdominal pain upon missing a meal. This pain was aggravated by alcohol.

Rear Adm Ocie B Morrison Jr MC USA Commanding Officer From the Pathology  
Service Capt Wilmot F Pierce MC USN Chief

**Physical Examination** The patient was 67 inches tall and weighed 160 pounds. His temperature was 99° F, pulse, 80 and blood pressure, 116/78 mm/Hg. He was well developed, well nourished, and in no acute distress. One examiner thought that there was slight thickening of the walls of the retinal arterioles. Other than this, there were no abnormalities of the head or neck. His chest was normal in size and shape. Loud expiratory rales were heard at the left base of the chest. His heart was not enlarged to percussion; no murmurs were heard, but the second sound, just to the left of the sternum at the level of the 5th interspace, was split. His pulse was totally irregular and there was a pulse deficit. His hands were cool and damp and fine tremors of his outstretched fingers were noted. There were no other significant physical findings.

**Laboratory Studies** Hemoglobin was 14.5 grams per 100 ml and the leukocyte count was 6,300. Sedimentation rate was normal. The urine was clear, alkaline, had a specific gravity of 1.020, normal albumin and sugar, and there were from 1 to 2 leukocytes per high power field. The serum cholesterol was 294 mg per 100 ml. PPD (first and second strengths) tuberculin tests and the Kahn test for syphilis were negative.

A roentgenogram of the chest in the posteroanterior position showed a slight prominence of the heart in the region of the left ventricle, the widest diameter measuring 14 cm in comparison with 29 cm for the widest intrathoracic diameter. Old healed fibrotic disease was evident in the right apex, and there was an increase in markings in the right lower lung field. Oblique views with barium swallow showed no definite chamber enlargement. Cholecystography indicated normal function without evidence of cholelithiasis.

An electrocardiogram recorded an auricular rate of 60, a ventricular rate of 70, and a sinus tachycardia with frequent runs of many multifocal ventricular premature beats from as many as five different foci (fig. 1). At times as many as nine consecutive ventricular premature beats appeared. The T waves were inverted in leads 3 and V<sub>4</sub>.

**Course in Hospital** Except for 99° F on admission the patient's temperature was not above 98.6° throughout his stay in the hospital. Pronestyl (brand of procaine amide hydrochloride) 1,000 mg daily in four doses was started when he was admitted, and this was gradually increased to 4,000 mg daily by 20 December. An electrocardiogram on 3 January showed fewer premature beats but widening of the QRS complexes. The dose of Pronestyl was diminished to 750 mg four times a day. A basal metabolic rate on 10 January was plus 17. The patient was completely asymptomatic up and about on the wards and he was allowed to leave the hospital on regular liberty until 24

January On that day when he was walking to the hospital, after spending the night at home, he had severe epigastric pain and vomited once. Another electrocardiogram showed some increase in prominent Q waves but physical examination revealed no abnormalities other than an irregular pulse. In a gastro-intestinal

Figure 1 Electrocardiogram showing multiple multifocal ventricular premature beats

roentgenographic series on 8 February, inconstant spasm and a crater measuring 1 cm in diameter were demonstrated in the prepyloric area of the stomach, stomach peristalsis was sluggish, and there was minimal residual barium in five hours. The esophagus was normal. The cardiac shadow in these films was enlarged in all diameters. Therapy with Amphogel (brand of a suspension of aluminum hydroxide) and belladonna was instituted and very soon his abdominal pain disappeared. Fluoroscopy on 3 March showed only slight spasm in the prepyloric portion of the stomach, and at intervals, this region filled out well and peristalsis was observed to pass through it.

On 17 January a clinical board concluded that further active duty was contra indicated and recommended that he appear before a Physical Evaluation Board. The diagnosis was ventricular premature contractions cause unknown.

On 7 March, he died while asleep during a "sort of convulsion."

### DISCUSSION

Doctor Greer: A young man 33 years old, was found to have an irregular pulse when he was being examined for re-enlistment in the U. S. Navy and he was admitted to the hospital for study. He had no complaints at the time and the only positive finding in a review of systems was abdominal pain that was said to occur when his stomach was empty. The physical examination revealed questionable sclerosis of the retinal arteries, loud expiratory rales at the left lung base, a split second heart sound at the left sternal border, totally irregular pulse, cool damp palms and a fine tremor of the outstretched fingers. The results of laboratory examinations were within normal limits except for a slightly elevated blood cholesterol. A roentgenogram of his chest revealed some prominence of the left ventricle, evidence of old healed fibrotic disease in the right apex and some increase in markings in the right lower lung field. Cardiac fluoroscopy did not reveal any significant chamber enlargement. Roentgenograms of the gallbladder were negative. The electrocardiograms showed an auricular rate of 60 and a ventricular rate of 70 with numerous and multifocal premature ventricular contractions, sometime as many as nine at a time. This makes one think that the many consecutive ventricular components were probably runs of ventricular tachycardia rather than just simple premature ventricular contractions.

The course in the hospital was very uncomplicated. The patient was given Pronestyl in rather large doses and following this there were fewer premature ventricular contractions. His basal metabolic rate was plus 17. A peptic ulcer was discovered while he was under observation and this responded well symptomatically. According to the report the second gastro intestinal series showed some improvement. A repeat roentgenogram of the chest showed the heart to be enlarged in all diameters. He appeared before a clinical board with a diagnosis of ventricular premature contractions, cause undetermined, and on 7 March he died while asleep during a "sort of convulsion." There are several things that I would like to ask. First of all I would like to know if he was overweight. Do you happen to know his weight?

Doctor Pierce: He weighed 160 pounds and he was 67 inches tall.

Doct. Greer: Was his blood Kahn test negative?

Doctor Pierce: Yes, the Kahn was negative.

Doctor Greer: And he was not gastroscopied?

June 1957)

# CLINICOPATHOLOGIC CONFERENCE

859

Doctor Pierce He was not

Doctor Green: It seems that the occurrence of premature beats was the main reason that this man was in the hospital, and premature beats are not too important clinically unless they do occur from multiple foci and occur frequently. It is said as I mentioned before, that runs of more than three consecutive premature ventricular contractions are pretty good evidence of paroxysms of ventricular tachycardia. When such contractions occur from multifocal areas, I think one can fairly safely say that there is organic heart disease. We are, occasionally, unable to determine the underlying cause of such heart disease, but I think these findings do indicate advanced myocardial disease and I think that anytime they occur there is the possibility of impending ventricular tachycardia leading to ventricular fibrillation. Actually there is not much else to go on in this case. There was no hypertension. There was no electrocardiographic evidence of myocardial damage in the sense of infarction although because of the premature beats myocardial disease probably did exist. We have no evidence of thyrotoxicosis. He had a tremor, but he had cool moist hands and thus is against thyroid disease, and an examination of the neck was negative. The Kahn test was negative, so syphilitic heart disease is also rather remote. So I think that probably if we are going to say that the man had heart disease it leaves us with arteriosclerotic heart disease, and this is uncommon in a young man of 33 years. However, considerable investigation of coronary artery disease in young men has been carried out by Yater and associates<sup>1</sup> who reported over 800 cases in men ranging from ages 18 to 40 years, and by French and Dock<sup>2</sup> who reported 80 cases. The findings were about the same: 90 per cent of the patients were overweight, 50 per cent died during vigorous effort and 10 per cent died during sleep. Arteriosclerosis of the coronary arteries was found in all but there was generalized arteriosclerosis in only a very small group. So this is a localized, selective type of arteriosclerosis. In 80 autopsies on these young men 59 per cent showed old infarction and only 19 per cent showed new infarction. All died suddenly and it is interesting to note that very few of the men who died had cardiac hypertrophy. Here we have a man who died suddenly and I think that probably a few words should be said about sudden death in young men. It is distressing to the doctor when a young man whom he is treating dies. I think that the responsible mechanism for sudden death is irreversible cerebral anoxia. It results from sudden local traumatic metabolic toxic or vascular damage to the brain. There may be exsanguinating hemorrhage resulting in medullary anoxia, or hemorrhage into the pericardial sac with tamponade. A massive pulmonary embolus can cause obstruction to blood flow and lead to sudden cerebral anoxia that can cause sudden death. Ventricular asystole or fibrillation can cause sudden death. Many times when death occurs suddenly the pathologist finds nothing to explain the cause. Death may also be caused by cessation of the heart beat that can result from ventricular fibrillation or cardiac standstill. In animal

experimentation when a coronary vessel is tied, electrocardiograms reveal that death is due to ventricular fibrillation. We also know from electrocardiographic evidence that patients in ventricular fibrillation die suddenly. The commonest cause of sudden death is vascular disease of the heart. A ruptured ventricle, complete heart block, ruptured aortic aneurysm, perhaps ventricular fibrillation, and sometimes quinidine therapy are causes of sudden death. Cerebral complications can also cause sudden death. Diseases of the digestive tract and urinary tract can also lead to sudden death. In 60 to 80 per cent of the sudden deaths due to cardiovascular disease, coronary arteriosclerosis is found. It is also interesting to note that studies of a large number of young men who died suddenly showed no evidence of recent infarction and frequently there was no evidence of coronary occlusion but in all the cases there was evidence of coronary arteriosclerosis.

I do not believe that this man had valvular heart disease because he had no murmurs. The commonest valvular disease to cause sudden death is calcific aortic stenosis. Cerebrovascular accidents are not very common causes of sudden death. In fact, about the only cerebral lesion causing sudden death is rupture of an aneurysm of the basilar artery. An embolus or hemorrhage into the brain does not cause death for 12 to 14 hours; usually it is 2 to 14 days before death occurs. Cerebral embolism occurs most commonly with heart disease. In children, rheumatic heart disease and subacute bacterial endocarditis and in adults, auricular fibrillation and coronary thrombosis are the two most frequent causes of this. We have several distinct possibilities for the cause of this man's death. In reverse order, I think that a pulmonary mechanism is not too likely. If he had had a pulmonary embolus, it would have to come from the right side of the heart and thrombi in the right side of the heart, especially from studies of young men, are not nearly as common as thrombi in the left side. As far as gastrointestinal disease is concerned, there is not much to go on. The man apparently had an ulcer; it was prepyloric; it might have been malignant but it improved under treatment. We have no evidence that blood came either from the mouth or from the rectum when he died but I suppose that he might have exsanguinated. May I ask who saw him die? Did a medical officer see him die?

Doctor Pierce: He died at home.

Doctor Greer: This sort of convulsion must have been the words used by his wife.

Doctor Pierce: Yes.

Doctor Greer: Well, it is difficult to diagnose from a wife's opinion as to how her husband died. Considering a neoplasm, he might have had a metastatic neoplasm from a carcinoma of the stomach but that is not likely. So actually, we are left with cardiovascular death. I think it is unlikely that this was due to myocarditis. We have no

June 1957)

# CLINICOPATHOLOGIC CONFERENCE

861

evidence that he had infection or postinfectious diphtheritic or rheumatic myocarditis. This could account very well however, for the numerous premature ventricular contractions. He also had no symptoms of heart failure although there was roentgenographic evidence of a heart enlarged in all diameters. We have no evidence that there was dyspnea or ankle edema. There is a remote possibility that there could have been some pericardial involvement, or that he could have had metastatic or primary tumor in the pericardial sac or the myocardium. It is also possible that this man could have ruptured a ventricle into the pericardium causing cardiac tamponade. I believe that the man died from coronary arteriosclerosis. I think that the cause of death was ventricular fibrillation.

Doctor Joraszewski: Apparently the patient was surveyed with the diagnosis of ventricular premature contractions. I don't see why any body would do that if his cardiac shadow increased in size from the time he was admitted. Was he discharged from the service?

Doctor Pierce: He was waiting to hear from the Physical Examination Board when he died.

Doctor Joraszewski: What I am trying to bring out is why he had cardiac enlargement from the time of admission to the second time that the chest films were taken. There is no mention here of any kind of examination of the chest circulation times, venous pressure determinations or anything like that. I don't believe he had arteriosclerotic heart disease. Cardiac arrest was due to either fibrosis of the lungs or a tumor of the heart either primary or secondary.

Doctor Gorlin\*: Well, I would agree that this is a most unusual course in a man of 33. I would think that he had some systemic type of infiltrative disease of the heart but I don't know where to begin with the amount of information that is presented. It was initially thought that there was acute change in heart size as well as arrhythmia.

Dr. Greer's diagnosis

Coronary arteriosclerosis and ventricular fibrillation

Dr. Joraszewski's diagnosis

Fibrosis of the lungs or heart tumor, either primary or secondary

Dr. Gorlin's diagnosis

Infiltrative disease of the heart

## PATHOLOGIC FINDINGS

Doctor Pierce: At autopsy the heart weighed 500 grams. Patchy gray opacities somewhat granular in appearance were evident over the epicardium of the left ventricle. All the chambers of the heart

Capt. Edward J. Joraszewski, MC, USN, Medical Service  
\*Lt. Richard Gorlin, MC, USNR, Medical Service

were dilated, particularly the left ventricle. The right auricle was moderately dilated. The endocardium of the papillary muscles of the right ventricle was slightly roughened by pinhead-sized glistening gray nodules. Similar but more numerous translucent nodules were incorporated in the endocardium of the left ventricle particularly concentrated below the anterior cusp of the aortic valve. The myocardium of the right ventricle was thin and pale and there were a few broad gray scars on the cut surfaces. The myocardium of the interventricular septum was about average in thickness but on sectioning instead of the usual red-brown color the cut surfaces were streaked gray yellow gray red yellow and red. No normal appearing myocardium could be seen grossly. In the left ventricle the myocardium was somewhat thin particularly toward the apex, and the cut surfaces were somewhat mottled deep red, red yellow gray yellow and gray. Numerous dense gray scars up to 1.5 cm in size were scattered throughout. The myocardium generally was flabby and somewhat friable. The coronary arteries were somewhat thickened and rigid and there were numerous yellow atheromatous intimal plaques. The lumens were somewhat diminished but nowhere was there any evidence of occlusion by thrombi, plaques or emboli.

The lungs were somewhat edematous. There were some apical adhesions. A small nodule was present just beneath the pleura of the right lower lobe on the lateral aspect 0.6 cm in diameter. Dense fibrous adhesions were present between the visceral and parietal pleura of the right lower lobe.

The liver weighed 2,200 grams. Glistening translucent minute gray opacities were scattered over the cut surfaces and seemed to follow the distribution of the large vessels. The spleen weighed 400 grams and was soft. No nodules were evident.

A shallow ulceration was present on the lesser curvature of the stomach, approximately 1 cm proximal to the pyloric ring. This was 0.7 cm in diameter and there was some puckering of the adjacent gastric mucosa. Mild gray thickening was evident on the serosal surface opposite the ulceration. There were no abnormalities of any other portion of the gastro-intestinal tract.

There was moderate enlargement of all lymph nodes, especially those in the peritoneal cavity and particularly those about the bile ducts. Except for mild atheromatous changes of the aorta and of the arteries at the base of the brain there were no significant gross findings in any of the other tissues.

Histologically there were granulomatous lesions in almost every organ of the body (fig. 2). These lesions were characteristic of sarcoidosis. No pathogenic organisms were isolated from the cultures of tissue taken at the time of autopsy and special stains showed no acid fast organisms or fungi in the tissues. A hamster was inoculated with material from a lymph node. This animal killed six weeks later showed no significant tissue alterations.

Figure 2 Sarcoid nodules in lung ( $\times 5$ )

The heart was extensively involved by the granulomatous process (fig 3) and in addition there were extensive regions of fibrosis some with hyalinization. There was no particular concentration of the lesions in any of the divisions of the heart. The right and left ventricles papillary muscles and interventricular septum were all sites of these lesions. Necrosis was not a feature of any of these lesions. It is estimated that about one third of the myocardium was involved, either by scarring or by the granulomatous lesions.

In sections through the gastric ulcer epithelium covered the entire surface of the crater but there was loss of submucosa, and muscularis mucosa and a portion of the muscularis. The epithelium lay on a very thin layer of smooth muscle fibers. Considerable infiltration of the underlying muscle with lymphocytes and large mononuclear leukocytes had occurred, and the vascularity in this portion of the wall was increased. Thickening of the serosa had occurred with proliferating connective tissue. Numerous granulomatous lesions similar to those seen in the heart and the other tissues were evident in the mucosa submucosa and the muscularis mucosa of the stomach proximal to the ulcer (fig 4).

Myocardial sarcoidosis is not a common cause of sudden and unexpected death. On the other hand involvement of the heart, either directly as in this case or through the pulmonary fibrosis associated with this disease does occur quite frequently. In the 92 autopsied cases collected by Longcope and Freiman<sup>3</sup> the heart was directly invaded by the granulomatous lesions in 18 (20 per cent). Five of these patients had died suddenly and unexpectedly. Abnormal electro

Figure 3. Myocardium and epicardium showing sarcoid nodules, fibrosis, and cellular infiltration. ( $\times 10$ )

Figure 4. Sarcoid nodules in submucosa of the stomach. ( $\times 10$ )

cardiograms in the course of sarcoidosis are reported fairly frequently in the literature in various series which have been published, abnormal electrocardiograms are the rule. This is due in most instances to damage resulting from pulmonary arterial hypertension. Inasmuch as involvement of the heart either primarily or secondarily can lead to myocardial failure this is a significant cause of death in patients dying directly of sarcoidosis. Myocardial involvement in the reported cases has varied from a few solitary nodules to extensive infiltration.

Involvement by sarcoidosis of the gastro-intestinal tract especially the stomach and duodenum probably occurs fairly frequently. Sirak<sup>4</sup> collected 12 cases from the literature and added one of his own. In these 13 cases there were ulcers of the lesser curvature in 3 and ulcer of the duodenum in 1. Other effects are antral deformities, pyloric narrowing or deformity, constriction of the duodenum and linitis plastica.

#### Pathologic diagnoses

1 Sarcoidosis, with extensive fibrosis involving the myocardium, lymph nodes, lungs, liver, spleen, bone marrow, kidneys, prostate gland, stomach, thyroid gland, dura, and leptomeninges.

2 Prepyloric ulcer, lesser curvature of the stomach.  
Healed, with mild, chronic, interstitial inflammation.

ever if I did not ou line for you a few of the highlights of his life to indicate why this hospital is being named for him

General Ireland was born in 1867 in Columbia City Ind approximately 200 miles from Fort Knox the son of a family doctor At the age of 23 he received an M D degree from the Detroit College of Medicine and one year later another from Jefferson Medical College in Philadelphia That same year 1891 he applied for a commission in the Army Medical Corps and was the only one of 10 candidates to be commissioned Fifty-nine years later in 1952 at the age of 85 he died and was buried in Arlington

*Major General Merritte W Ireland, Surgeon General United States Army from 4 October 1918 to 31 May 1931 A large replica of this portrait now hangs in the main lobby of Ireland Army Hospital.*

General Ireland's early service was mostly on posts in the West but during the Spanish American War he went to Cuba with a division hospital and then to the Philippines for a tour of duty From 1902 to 1912 he served in the office of The Surgeon General much of the time as Chief of the Personnel Division Here he garnered experience and background which was to serve him to good stead in later years as Surgeon General

June 1957)

# IRELAND ARMY HOSPITAL

869

In World War I he became Chief Surgeon of the American Expeditionary Force, and won the highest commendation from his close personal friend, General Pershing. At the end of that war he was appointed Surgeon General and served in that capacity for 13 years until his

*Following the climax of the dedication ceremony Mrs Ireland stands in front of the dedicatory plaque which she has just unveiled with her son Doctor Paul M Ireland and Major General Silas B Hays The Surgeon General of the United States Army*

retirement in 1931. During his administration Walter Reed and Letterman Hospitals were rebuilt and William Beaumont Hospital was constructed. He established the Medical Field Service School in which thousands of officers and enlisted men of the Army Medical Service

have been trained And it was he who brought interns into our Army hospitals and began the professional training program of which we are so proud

In a lecture which he gave in Philadelphia in 1939 at the age of 72 General Ireland said "That I am the Army has made me what honors have come to me to brighten and ennoble my life, however undeserved were the free gifts of my comrades in the Army and of my Government The Army has always been my first love and I shall go to my grave believing that it is the truest exponent of American democracy and that in its Medical Department are to be found the highest ideals and principles of the healing art

Both the Army Medical Service and Fort Knox have reason to be proud to dedicate this hospital today to one who treasured and revered the Army as did Major General Merritte W Ireland

### TEACHERS OF MEDICINE

One of the diseases of our society is this erroneous belief that the brave new world will come to pass by miracles of structural design and intricate organisation alone Plans there must be but personalities must take precedence of plans The basic essential is to ensure that medical students both undergraduates and post graduates are associated with (not just taught by) those whose lives and work are examples of excellence in scholarship and professional skill These teachers must be ever dissatisfied with their efforts critical of themselves and others forever scheming and striving to test the truth of what appears to be known and planning to enlarge knowledge Among such there is no room for the complacent the arrogant the staunch upholder of tradition and the stout defender of the status quo The quality of our teachers is all important and a heavy responsibility rests on those who have to select the academic staffs and consultants responsible for medical education

# ROLE OF PHYSICIANS IN RECOMMENDATIONS OF COMPASSIONATE PERSONNEL ACTIONS

JAMES J GIBBS Major MC USA  
RALPH W MORGAN Major MSC USA

**A** WELL-KNOWN aspect of Army life is the lack of choice in the duration or location of duty assignments. This may produce stressful situations if members of the serviceman's family are unable to adjust to a particular environment or if his impending or actual separation from the family comes at a time when his presence is necessary because of serious illness, death, legal difficulties, or other problems in the immediate family. Aware of its responsibilities, the Army has provided for the alleviation of such family hardship through compassionate personnel actions. These include emergency leave, extension of such leave, deferment of overseas assignment, and compassionate reassignment.

The magnitude of this problem is emphasized by the approximately 2,000 requests for compassionate personnel action which reach the Office of The Adjutant General of the Army each month. This includes only those requests which are required by Army regulations to be processed by the Emergency Return Section of The Adjutant General's Office at Department of the Army level. Many others are voted upon by major commanders so that the total far exceeds 2,000 per month. Because the majority of requests for such actions involve physical and/or mental illness of a member of the serviceman's family, military and civilian physicians are frequently called upon for statements concerning the medical status of the dependent.

Medical reports frequently contain vague, incomplete information and unrealistic recommendations which result in a delay of administrative action, and reassignments by the serviceman and his family when requests are not favorably considered. A simple statement of the presence or absence of a physical or mental illness may present no difficulty, however, the emotional, legal, economic, social, and administrative aspects of a family medical problem may introduce complications which must be considered in the medical report.

From Professional Division Office of The Surgeon General Department of the  
Army Washington D C

In addition to safeguarding the serviceman and his family, the final decision must also consider the necessity of accomplishing the military mission. Whether compassionate personnel action would aid or correct the situation and not foster overly dependent behavior and thus initiate or continue maladjustment of the family to military life must also be considered. It should be recognized that in many cases a hardship exists which cannot be remedied by leave or reassignment but only by discharge from the service.

Each request for compassionate personnel action is handled on an individual basis. From an administrative standpoint it would be advantageous to include in *Army Regulations* the specific criteria used in determining the merits of each case. However, illness and other vicissitudes, with their diverse effects upon individuals, and the innumerable situations that can produce severe hardships, make it impossible to cover each situation. Therefore regulations can be used only as a guide.

### RETURN OF PERSONNEL TO U S

#### Reasons for Return

AR 608-40 states that the following or related cases will be considered as reasons for return of the serviceman to the United States or Territory of residence under emergency conditions for a period of 30 days:

a. When the death of the wife or unmarried minor child of a serviceman has been verified by the American Red Cross.

b. When the return of an individual will contribute to the welfare of a dying member of the immediate family (immediate family to include only father, mother, a person *in loco parentis*\* spouse, children, brother, sister, or only living relative). An example would be an elderly mother with a chronic heart condition which has reached a terminal stage.

c. Where, through the death or serious illness of, or accident to, a member of the individual's immediate family, important responsibilities are placed on the individual which must be met promptly, cannot be accomplished from overseas, and cannot be discharged by any other individual. For example, a spouse who develops an acute overt psychosis, leaving three minor children unattended.

d. For other emergency situations which may not specifically meet the above requirements but where the failure of the individual to return would create a severe and unusual hardship.

---

\* *Per* o t be c det d n loco parent s mu t have r pl ced ad a umed all of th oblig t o s of the natural pare t of the memb r (incl ding financial support) f r th bulk of th member s minor ty

on either himself or his family and the return is required within a period of 20 days

### **Return of Serviceman Requested by Family**

The procedure to be followed when family members request the return of military personnel to the United States or Territory of residence is as follows

a A request for return is submitted by family members to the local chapter of the American Red Cross. The American Red Cross obtains all information available, including medical documentations when indicated. The local chapter then forwards a report to its National Headquarters which in turn submits it to The Adjutant General, Department of the Army, Washington 25, D. C., or Commanding General of an area where authority from The Adjutant General is not required.

b Requests which reach the Emergency Return Section of The Adjutant General's Office are carefully reviewed. If information is incomplete, final decision may be delayed until additional reports are obtained. Favorable consideration results when the American Red Cross welfare reports and the medical statements indicate that the case has merit, and that the current Army mission allows the granting of the request. The officers of the Emergency Return Section are placed in a very difficult position if the physician lacks a proper appreciation and understanding of the military problem. The staff of the Emergency Return Section has access to expert medical opinion from the Office of The Surgeon General to assist them in evaluating medical problems.

*Case example 1* A five year old dependent daughter of a serviceman was diagnosed by a medical officer as suffering from bronchial asthma. He wrote a strong medical statement recommending that the serviceman be reassigned to a post in Arizona or Nevada for this reason. This recommendation was made in spite of the fact that the child had never resided in these States and her asthma appeared to be relatively well controlled on medication. Upon the advice of the Medical Consultant to The Surgeon General, this request for compassionate transfer was refused. The serviceman, incensed at what appeared to him to be a medical decision being made by a physician who had never seen his child, appealed to his Congressman, who also questioned the Medical Consultant's recommendation in this case.

*Comment* It can be seen that this medical recommendation resulted in the serviceman and his wife feeling as though an injustice had been done, even though sound medical experience dictated this course of action. Had the physician encouraged the parents to accept their child's illness and to follow the prescribed treatment it would have been better for all concerned.

In addition to safeguarding the serviceman and his family, the final decision must also consider the necessity of accomplishing the military mission. Whether compassionate personnel action would aid or correct the situation and not foster overly dependent behavior and thus initiate or continue maladjustment of the family to military life must also be considered. It should be recognized that in many cases a hardship exists which cannot be remedied by leave or reassignment but only by discharge from the service.

Each request for compassionate personnel action is handled on an individual basis. From an administrative standpoint, it would be advantageous to include in *Army Regulations* the specific criteria used in determining the merits of each case. However, illness and other vicissitudes with their diverse effects upon individuals and the innumerable situations that can produce severe hardships make it impossible to cover each situation. Therefore regulations can be used only as a guide.

### RETURN OF PERSONNEL TO U S

#### Reasons for Return

AR 608 40<sup>1</sup> states that the following or related cases will be considered as reasons for return of the serviceman to the United States or Territory of residence under emergency conditions for a period of 30 days:

a When the death of the wife or unmarried minor child of a serviceman has been verified by the American Red Cross.

b When the return of an individual will contribute to the welfare of a dying member of the immediate family (immediate family to include only father, mother, a person *in loco parentis*\*, spouse, children, brother, sister, or only living relative). An example would be an elderly mother with a chronic heart condition which has reached a terminal stage.

c Where through the death or serious illness of or accident to a member of the individual's immediate family, important responsibilities are placed on the individual which must be met promptly, cannot be accomplished from overseas, and cannot be discharged by any other individual. For example, a spouse who develops an acute overt psychosis leaving three minor children unattended.

d For other emergency situations which may not specifically meet the above requirements but where the failure of the individual to return would create a severe and unusual hardship.

---

\* Persons to be considered *in loco parentis* must have replaced and assumed all of the obligations of the natural parent. If the member (including financial support) is the bulk of the member's family.

on either himself or his family and the return is required within a period of 20 days

#### **Return of Serviceman Requested by Family**

The procedure to be followed when family members request the return of military personnel to the United States or Territory of residence is as follows

a A request for return is submitted by family members to the local chapter of the American Red Cross. The American Red Cross obtains all information available, including medical documentations when indicated. The local chapter then forwards a report to its National Headquarters which in turn submits it to The Adjutant General, Department of the Army, Washington 25, D. C., or Commanding General of an area where authority from The Adjutant General is not required.

b Requests which reach the Emergency Return Section of The Adjutant General's Office are carefully reviewed. If information is incomplete, final decision may be delayed until additional reports are obtained. Favorable consideration results when the American Red Cross welfare reports and the medical statements indicate that the case has merit, and that the current Army mission allows the granting of the request. The officers of the Emergency Return Section are placed in a very difficult position if the physician lacks a proper appreciation and understanding of the military problem. The staff of the Emergency Return Section has access to expert medical opinion from the Office of The Surgeon General to assist them in evaluating medical problems.

*Case example 1* A five year old dependent daughter of a serviceman was diagnosed by a medical officer as suffering from bronchial asthma. He wrote a strong medical statement recommending that the serviceman be reassigned to a post in Arizona or Nevada for this reason. This recommendation was made in spite of the fact that the child had never resided in these States and her asthma appeared to be relatively well controlled on medication. Upon the advice of the Medical Consultant to The Surgeon General, this request for compassionate transfer was refused. The serviceman, incensed at what appeared to him to be a medical decision being made by a physician who had never seen his child, appealed to his Congressman, who also questioned the Medical Consultant's recommendation in this case.

*Comment* It can be seen that this medical recommendation resulted in the serviceman and his wife feeling as though an injustice had been done, even though sound medical experience dictated this course of action. Had the physician encouraged the parents to accept their child's illness and to follow the prescribed treatment it would have been better for all concerned.

## FOREIGN SERVICE

## Personal Hardship

There is no specific regulation which deals with compassionate reassignment. Consequently most of the criteria stated in AF 614 30,<sup>2</sup> which deal with overseas deferments, are applied to such cases. This regulation states, in effect, that personnel alerted for or on orders to overseas commands, may be granted temporary deferment when compliance with such orders will impose hardship upon the individual or his family under the following criteria:

a Illness of a member of the immediate family of the individual provided that

(1) In the opinion of the attending physician

(a) The illness is such that the patient cannot reasonably be expected to live longer than one year

(b) The illness is of such a nature that the individual's presence is an important factor in the patient's recovery whereas his immediate departure might have a serious adverse effect upon the patient. A case having merit under this criterion would be that of a dependent recovering from a severe illness of recent onset such as coronary thrombosis

(c) The legal wife of the individual is in her seventh month of pregnancy (this criterion is utilized only for overseas deferment)

b Financial or domestic hardship involving the immediate family, provided that the individual's presence during the period of his deferment will effect reasonably permanent relief which cannot be achieved by other satisfactory means

## PRINCIPLES

Each request for compassionate personnel action requires documentation and the exercise of sound judgment before any action is taken. The physician's statement becomes of paramount importance in any such action and if he is to discharge satisfactorily his responsibility, he must be aware of certain stated and implied principles that in the final analysis determine the decision rendered in each case.

*The expeditious accomplishment of the Army mission is of primary importance.* When the medical officer makes a medical recommendation he may not be primarily concerned with the feasibility of his recommendation. A medical recommendation which is not consistent with the mission of the Army sets up a chain reaction which does not serve the best interests of the patient or the service. In case example 1 it is clear that the

Army could not be expected to utilize efficiently an individual whose assignment would be permanently limited to two states in the Southwest. Moreover, the normal vicissitudes of the service must be shared by all. Resignation or application for hardship discharge would be the proper solution for long term, family medical problems which do not lend themselves to service life, rather than expecting others in the Army to assume an unfair share of overseas or isolated assignments.

*The requested action must alleviate mental anguish and/or enable the serviceman to perform an emergent legal obligation for which he has primary responsibility.* The usual purpose of compassionate personnel actions is to relieve mental anguish on the part of the member and/or persons in his family. Mental anguish is a subjective state in which the individual suffers intense and painful psychic distress, such as guilt, anxiety, depression, and the like. The effect upon the individual of mental anguish ranges from temporary loss of emotional control through multiple somatic symptoms, to few or no external manifestations. Usually, however, there is great preoccupation with the family problem, which often results in inattention to duty and a marked decrease in motivation toward military service.

If the mission permits, it is to the benefit of the Army to alleviate the mental anguish of the member through a compassionate personnel action. In some cases because of marital estrangement, immature behavior patterns, or other reasons, the serviceman may not desire emergency leave or compassionate reassignment. However, when the serviceman has a primary legal responsibility which cannot be discharged without his presence, the proper headquarters may issue appropriate orders returning him to the United States even though he expresses no desire to do so.

*Case example 2* A serviceman had not communicated or lived with his wife for five years although he continued to support her and their child. When his wife became acutely psychotic while he was overseas, his emergency return was requested for the purpose of arranging for commitment of his wife and care of his child. He, however, showed no interest in returning to the Continental United States, but was ordered to do so because no one else was available to assume his legal obligation to care for his family.

*Severe objective hardships which can be alleviated only by the presence of the member must exist.* Since mental anguish is so subjective and highly personalized, the causative factors of the external stress necessary to induce mental anguish are widely among individuals. In view of this, it is not possible to list objective situations which will always result in mental anguish.

and even appear to be a likely candidate for psychiatric treatment. Many therapists state that the serviceman's return home is required before treatment can be successful. If we think of psychiatric treatment as a method for helping the patient achieve more maturity and develop better ways of adjusting to life's many frustrations and adversities with less discomfort, the serviceman's return home because of her emotional illness could be a deterrent to successful treatment by enhancing the amount of secondary gain by decreasing or eliminating motivation for treatment and by fixating and encouraging a pathologic pattern of behavior.

*Case example 4.* A recent case having some relationship to this point of view was that of a serviceman who requested a compassionate reassignment from his overseas duty station to a specific unit stationed in a fairly large city because of his wife's health. His wife's emotional illness dated back to 1940 when she first required treatment. She had required therapy intermittently since then and usually as the result of her husband's absence. Except for one brief period she refused treatment from Army psychiatrists. She never accompanied or joined her husband on his overseas tours because of her illness and the advice of her physician.

This patient had been seen by a number of psychiatrists and physicians. There was general agreement that she had chronic severe neurosis characterized by multiple phobias, depression, and panic states. She was described as an extremely dependent and insecure person who was unable to adjust well to responsibilities and to being alone.

*Comment.* While it is clear that the wife in this case and her husband both were suffering considerable mental anguish because of their enforced separation, it is also evident that the assignment of this serviceman as requested would not be equitable to others and would in no way contribute to a permanent solution to a problem which was essentially unsolvable within the Army environment. In this case resignation from the service was offered and was accepted by the serviceman as a solution to the problem his wife's emotional disability presented.

## PRACTICAL SUGGESTIONS

### Treatment

The medical officer must appreciate the fact that separation of a serviceman from his family may induce hardship, inconvenience, discomfort or anxiety. It is highly improbable that anyone, whether physician or layman, can completely alleviate these conditions. On the other hand, it is equally unreasonable to believe that the physician has nothing of value in his armamentarium for dealing with the emotionally distraught

dependent. This may not necessarily require medication or other formal treatment procedure, but may consist only of the reassurance that the patient gains from a thorough evaluation—followed by a calm summation of the facts and forthright discussion as to the course of action to be followed.

If, during the course of those procedures, the physician clearly defines the reality of the patient's situation and firmly indicates, when he believes the facts so warrant, that the serviceman's return is not necessary, the patient frequently will have a reasonable chance of remaining effective. Somatic complaints, or even true illnesses, are then less likely to become a route of escape. The patient is then better able to utilize her own emotional strengths and the variety of assistance which may be available from relatives or from various social service organizations.

Most therapeutic procedures will give discouraging results when the patient's presence in the physician's office is motivated not so much by incapacitating symptoms as by a desire for his support in requesting some type of compassionate personnel action. It behooves the physician to be alert to such a possibility if he is to be of service to his patient. His therapeutic efforts will be futile until he clarifies his position. When the patient has been informed that the doctor will prescribe treatment as indicated by his examination and will not give the patient the statement he or she desires unless indicated, the doctor and patient will no longer be working at cross purposes. This mutual understanding then may pave the way for constructive therapeutic endeavors.

Most medical officers will recall at least one case in which the patient failed to keep future appointments or in other ways indicated little motivation for further medical assistance after she had obtained a favorable medical statement—only to return at a later date when the request for compassionate personnel action was denied.

#### **Referral to Social Service**

When the dependent is so emotionally immature or upset that she does not accept a medical recommendation made in the foregoing manner, the physician is often tempted to make recommendations which are unjustified by the facts of the case because of a personal need to "do something," and because he is unaware of the many agencies which are usually available to assist him in cases of this nature.

When the physician has determined that a medical recommendation for compassionate personnel action is not justified, or he desires an objective study of the dependent's situation prior to making the actual determination, he will find that referral of the patient to a qualified social agency is usually quite

helpful. In hospitals referrals may be made to the Military Social Work Service or the American Red Cross Hospital Social Service. In small hospitals or in dispensaries in civilian communities the dependent can be referred to the local American Red Cross Chapter or other available social agency.

Social workers are often of distinct value in providing dependents with the emotional support they may require to continue functioning in times of illness or other stress, and in mobilizing community resources to help solve or alleviate the patient's problem. The physician who refuses to make an unjustified medical recommendation for a compassionate personnel action at the behest of an immature or neurotic dependent and who follows through by a referral to a competent social agency is acting in the best interest of the patient. The serviceman the Government and himself. Unless such referral is made the dependent often continues to "shop" for a medical recommendation to the detriment of herself and the medical facilities which she frequents—especially if she is ultimately successful in her efforts.

#### Content of Medical Recommendations

The content of the medical recommendations should conform to the principles of sound medical practice. It is most important for the doctor to use factual descriptions if his report is to reflect accurately his evaluation of the patient. The use of general terminology which can be interpreted in many ways and which does not indicate the degree of incapacitation seriously limits the value of a medical evaluation. Terms such as "anorexia" and "insomnia" only mean that the patient has difficulty in eating and sleeping. To say, however, that the patient lived on cigarettes and coffee to the point that she has lost 10 pounds within 2 weeks and has slept no more than 1 to 2 hours each night during the same period of time clearly communicates to someone else the severity of the symptoms.

Pertinent historical data should not be sacrificed for the sake of brevity. When compassionate personnel action of some type is being considered it is important to have an impression of the patient's past performance when confronted with a stressful situation. One may find that the patient reverts to habit patterns which could aggravate an organic illness or result in serious neglect of minor children. More often, however, it is apparent that the subjective complaints become aggravated in the absence of objective evidence that the illness has become more severe. Where the information requested is too voluminous or detailed for inclusion in an Army Red Cross report or a telegram it should be forwarded by the next most expeditious means.

No medical report is complete without mentioning treatment. In addition to the type and duration of therapy, the patient's

motivation and cooperation is worthy of comment since no treatment program is of value unless the patient adheres to it. Where secondary gain from illness is a factor it may at times be naive to assume that a patient will diligently follow the doctor's orders.

Diagnosis can usually be stated clearly, but the physician may be reluctant to make statements as to prognosis. Some estimation of prognosis is necessary in considering compassionate personnel actions to avoid premature or delayed assignment changes which hinder the effectiveness of the soldier and increase rather than decrease the mental anguish and hardship involved.

*Case example 5* The child of a serviceman was diagnosed as having acute leukemia. For medical reasons the family was not fully informed of the nearness of the child's death. The serviceman, upon receiving orders for overseas, complied with these orders, only to find it necessary to return within a few months in the final weeks of the child's life. Had the physician taken the initiative in this case in encouraging the serviceman to apply for deferment from overseas movement substantial mental anguish would have been saved this family and the business of the Government could have been conducted more efficiently.

The physician should not include in his medical statement unverified statements from the patient. Overtreatment in the form of recommending compassionate reassignment when an emergency leave would suffice, or otherwise letting the patient dictate the form and duration of treatment, should be avoided in the best interest of the patient and the service.

#### **Administrative Considerations**

Local policy accounts for wide variations in the manner in which medical statements are initially processed. In some facilities all medical statements must be routed through the Adjutant, in others the registrar or commanding officer of the medical holding detachment had this responsibility. In absence of policy in this regard the medical officer would be well advised to route all such statements through the administrative office responsible for the maintenance of the patient's records. This is to protect the medical officer and his unit commander against administrative or legal repercussions because of an unauthorized release of medical information. In case of patients not subject to military law, no formal medical statement should be released without first obtaining specific written permission from the patient, except under the provisions of paragraph 15 a, AR 345-20.

#### **Recommendations**

It is believed that by giving serious consideration to the principles already mentioned, part of the physician's dilemma

may be solved Based on these principles he may come to one of three conclusions regarding a request for compassionate personnel actions Proper recommendations can then be made as follows

- 1 The case has merit and favorable action is justifiable
- 2 The case lacks merit and favorable action is not necessary
- 3 The condition in question is chronic in nature and the problem it has created remains unsolvable within the Army environment The same may be true where the dependent has a character and behavior disorder which is so severe that the serviceman's absence inevitably results in the neglect of minor children economic disaster or antisocial behavior which realistically hinders the serviceman's performance of duty

### CONCLUSION

An attempt has been made to provide physicians with a proper appreciation of their role in recommending compassionate personnel actions in relation to members of the Army The military medical psychiatric social and administrative aspects of medical recommendations for such actions have been discussed and practical suggestions made in the writing of medical statements and for improving the care of patients seeking compassionate personnel actions

# ARMY TESTS FOR ASSESSMENT OF INTELLECTUAL DEFICIT

ERNEST K. MONTAGUE, *Lieutenant Colonel MSC USA*

HAROLD L. WILLIAMS, *Captain MSC USA*

ARDIE LUBIN, *Ph D*

CHARLES F. GIESEKING, *M A*

**T**HE estimation of cognitive deficit caused by illness is of importance to the military medical services. In the Army, all enlisted personnel take two tests of mental ability when they enter, and these tests can be used as estimates of the premorbid intellectual level of a patient. The same tests can be used after injury or illness to measure any intellectual deficit that results.

The first section of this article describes the tests administered at entry into the Army. The second section furnishes technical data for the assessment of intellectual deficit. The third section provides a basis for comparing scores on the Army Classification Battery with scores on the Wechsler-Bellevue scale.

## THE ARMY TESTS

At the present time each enlisted man takes two kinds of tests: (1) the Armed Forces Qualification Test (AFQT), which is used to estimate intellectual level, and (2) the Army Classification Battery (ACB), which is used for occupational classification. All enlisted men in the Armed Forces take the AFQT. However, the Air Force and Navy have developed their own classification batteries.

Both the AFQT and the ACB were developed from the Army General Classification Test (AGCT), which was administered to all Army enlisted men from 1940 to 1945. The AGCT was a spiral omnibus test (i.e., the items were arranged in order of increasing difficulty and a single score was obtained) using three types of items (spatial visualization, vocabulary, and arithmetic reasoning). This score was adjusted so that the general mean was 100, and the standard deviation was 20.

---

From Walter Reed Army Institute of Research, Walter Reed Army Medical Center, Washington, D. C. Col. Montague is now assigned to Office of the Surgeon General, Department of the Army, Washington, D. C.

The AFQT is also a spiral omnibus test. The scores are percentiles going from 0 to 100. This test has been revised periodically to take care of security leaks, obsolescence of items, revised standards and improved methods of testing. Forms 1 and 2 of the AFQT were used from 1950 to 1952. They contained the same three types of items found in the AGCT (verbal analogies, arithmetic reasoning, and spatial relations). Forms 3 and 4 of the AFQT were used from 1953 to August 1956. These forms introduced tool usage items. Altogether there were 100 items, 25 of each type. Forms 5 and 6 are now being used. They are essentially similar to Forms 3 and 4.

The ACB has been given to all enlisted men inducted into the Army since 1948. There are 10 tests in the ACB. These tests are used by the Classification Officer for assignment of Enlisted Men to various military occupations. As in the AGCT, the mean of each test is 100 and the standard deviation of each test is 20.

The ten ACB tests are described below. With the exception of the Radio Code Aptitude Test, all the ACB tests are in paper and pencil form.

### Army Classification Battery (ACB) Tests

**1 Reading and Vocabulary Test, RI 1 (PRT 1161) and RV 2 (PRT 1164)** This test contains a number of reading passages of one or more paragraphs. Several four alternative multiple choice items are based on the content of each paragraph. The reading matter varies from a simple description of Army camp activities to complex technical information. There are 53 items; the time limit is 25 minutes.

**2 Arithmetic Reasoning Test, AR 1 (PRT 1167) and AR 2 (PRT 1170)** In this test each item is an arithmetic problem presented verbally, with four alternative responses. Some items are based on scales, dials, tables, or graphs. There are 53 items; the time limit is 35 minutes.

**3 Pattern Analysis Test, PA 1 (PRT 1173) and PA 2 (PRT 1177)** In this test a two-dimensional pattern with numbered lines is presented along with the corresponding three-dimensional figure made by folding the pattern along the indicated lines. The edges of the figure are lettered. The examinee is required to identify the lettered edge of the figure corresponding to a numbered line in the pattern. The numbers in the pattern are the item numbers and the letters of the figure are used to form five alternative responses for each item. There are 50 items; the time limit is 20 minutes.

**4 Mechanical Aptitude Test, MA 5 (PRT 1157) and MA 6 (PRT 1158)** In this test each item consists of a figure illustrating

some physical principle and a verbal question with two, three, or four alternative responses. There are 45 items, the time limit is 15 minutes.

5 *Army Clerical Speed Test, ACS-1 (PRT 686) and ACS 2 (PRT 690)* This test consists of two parts, both highly speeded and administered with separate time limits.

(a) In Part I, Number Reversal (125 items) each item consists of two numbers. There are two alternative responses to indicate whether or not the second number is exactly the reverse of the first. The time limit is 5 minutes.

(b) In Part II, Coding (100 items), there is a key containing 10 words. Each word in the key has a number that is associated with it. Each item presents a word followed by the 10 alternative numbered responses in the key. The time limit is 5 minutes.

6 *Army Radio Code Aptitude Test, ARC-1 (PRT 78)* This is an auditory test, recorded on four phonograph records which include directions for the examinees. The first part of the test is composed of 270 learning exercises which are designed to teach the examinee the code signals for the three letters I, N, and T. These items are presented at approximately 4 to 7 words per minute. Immediately after the learning exercises, a test of 150 items is given to measure how accurately the three code signals can be recognized at varying speeds. The first 75 items are presented at approximately 15 words per minute, and the second 75 at approximately 21 words per minute. Responses are recorded on machine scorable answer sheets presenting the three alternatives for each item.

7 *Shop Mechanics Test, SM-1 (PRT 476) and SM-2 (PRT 477)* In this test each item presents a drawing illustrating some mechanical principle or tool usage, followed by a four alternative question. There are 40 items, the time limit is 15 minutes.

8 *Automotive Information, AI-1 (PRT 468) and AI-2 (PRT 469)* In this test each item is a four alternative question about the identification or operation of automobile parts. Many items are based on pictures or diagrams. There are 40 items, the time limit is 15 minutes.

9 *Electrical Information Test, EI-1 (PRT 691) and EI 2 (PRT 692)* In this test each item is a four alternative question on some element of electrical information. Many items are based on pictures or schematic diagrams. There are 40 items, the time limit is 15 minutes.

10 *Radio Information Test, RI 1 (PRT 693) and RI 2 (PRT 694)* In this test each item is a four alternative question on some aspect of radio information.

The AFQT is also a spiral omnibus test. The scores are percentiles going from 0 to 100. This test has been revised periodically to take care of security leaks, obsolescence of items, revised standards and improved methods of testing. Forms 1 and 2 of the AFQT were used from 1950 to 1952. They contained the same three types of items found in the AGCT (verbal analogies, arithmetic reasoning and spatial relations). Forms 3 and 4 of the AFQT were used from 1953 to August 1956. These forms introduced tool usage items. Altogether there were 100 items, 25 of each type. Forms 5 and 6 are now being used. They are essentially similar to Forms 3 and 4.

The ACB has been given to all enlisted men inducted into the Army since 1948. There are 10 tests in the ACB. These tests are used by the Classification Officer for assignment of Enlisted Men to various military occupations. As in the AGCT, the mean of each test is 100 and the standard deviation of each test is 20.

The ten ACB tests are described below. With the exception of the Radio Code Aptitude Test, all the ACB tests are in paper and pencil form.

### Army Classification Battery (ACB) Tests

**1 Reading and Vocabulary Test RV 1 (PRT 1161) and RV 2 (PRT 1164)** This test contains a number of reading passages of one or more paragraphs. Several four alternative multiple choice items are based on the content of each paragraph. The reading matter varies from a simple description of Army camp activities to complex technical information. There are 53 items; the time limit is 25 minutes.

RI	0 25	0 30	0 25	0 30	0 20	0 25	0 35	0 30	0 50	1 0

This standard table of intercorrelations was developed from five large samples of enlisted men available by 1951 (Numbers in the samples ranged from 500 to 3 561) All values are rounded to the nearest 0 05 except for two high coefficients where rounding off in either direction would distort the results<sup>2</sup>

In this article only the first five tests (RV, AR, PA, MA, ACS) of the ACB are considered There are a number of reasons for so doing (1) Time limitations It takes a little more than two and one half hours to administer just the first five tests (2) The first five tests are aptitude measures, whereas the last five are much more measures of achievement or skill (3) The scores for the last five tests are sometimes missing from Form 20

Table 2 presents some preliminary test retest data for two control groups on the first five tests of the ACB Samples were drawn from Ft Meade, Md, and from the patient detachment at Walter Reed Army Hospital

The Ft Meade sample consisted of all the enlisted men available for testing in a medical training unit The age ranged from 18 to 44, years of education, from 6 to 20, The rank, from private to master sergeant The test retest time ranged from 20 weeks to 403 weeks

The Walter Reed Army Hospital controls were a sample of enlisted patients from which all psychiatric patients and patients having a diagnosis of brain damage were excluded Years of education ranged from 5 to 18, rank, from private to master sergeant, and age, from 18 to 41 years The distribution of elapsed time between test and retest was similar to that of the Ft Meade sample, being 30 to 390 weeks In table 2, the retest mean,  $\bar{X}_2$ , for both control groups is slightly higher than the original mean,  $\bar{X}_1$   $\bar{D}$  is the average increase from  $\bar{X}_1$  to  $\bar{X}_2$  There is a minimum increase of about 1 point, apparently due to

schematic diagrams There are 40 items, the time limit is 15 minutes

Inasmuch as the AGCT is no longer in use it will not be discussed here

### Armed Forces Qualification Test (AFQT)

The correlation between the equivalent Forms 1 and 2 when taken on the same day is about 0.90. The correlation between Forms 3 and 4 is 0.93. Forms 1 and 2 correlated with Forms 3 and 4 about 0.85.

The great advantage of the AFQT is that all members of the armed services take it. However it is rather difficult to use the AFQT for the assessment of premorbid intelligence since it is not easy to obtain the AFQT score for many enlisted men. These scores are not regularly entered on Form 20 (Form 20 will always be found in the Record Jacket). Instead they are entered on DD Form 47 for inductees and DD Form 4 for enlistees. Since April 1956 these forms have been placed in the Record Jacket. Prior to April 1956 there was no requirement that the AFQT score be included in the Record Jacket. One copy of Form 47 is sent to the Surgeon General Department of the Army Washington 25 D C, ATTN MEDCS. It is held there for about a year and then stored in Alexandria Va (Unfortunately Form 47 is filed by place and date of induction rather than alphabetically or by Army Serial Number).

There are other difficulties in using the AFQT. It cannot be readministered to an enlisted man without permission from the Adjutant General. No test retest studies have been made where the time interval between test and retest was longer than a few days. Only a single score is available; there is no way to measure differential deficit. For these reasons and others we have turned to the ACB as a means of assessing mental deficit due to illness.

### Army Classification Battery (ACB)

The ACB when properly weighted usually can predict performance at various Army Schools (Radio Mechanics et cetera) with an average validity of about 0.6. Correlations with actual performance in the field run somewhat lower. The ACB inter correlations are given in table 1.

Frequently the clinical psychologist or medical officer is asked whether the patient's abilities are so impaired that he cannot be returned to his former duty. Theoretically the ACB scores made by a patient following illness could be used to help determine whether the patient could be returned to duty.

If the data in table 2 were truly representative of the Army population, how could they be used to assess the mental deficit due to brain injury or mental illness? How much must an ACB score drop (assuming adequate motivation) before there can be good evidence of mental deficit?

Let us assume that we have an ACB test where the mean of  $\lambda_1$  is 100, the mean of  $\lambda_2$  is 101, the standard deviations are each 20, and the test retest correlation is 0.70. Maximum sensitivity can be obtained by using the usual prediction equation

$$\hat{\lambda}_2 = a + b\lambda_1$$

where  $\hat{\lambda}_2$  is the predicted retest score,

$\lambda_1$  is the first test score,

$$b = r_{12} \frac{\sigma_2}{\sigma_1},$$

and  $n = \bar{\lambda}_2 - b\bar{\lambda}_1$

In this case,  $\hat{\lambda}_2 = 31 + 0.7\lambda_1$ . The error of prediction,  $\lambda_{2,1}$ , will equal  $\lambda_2 - \hat{\lambda}_2 = \lambda_2 - 31 - 0.7\lambda_1$ . The standard deviation of the error of prediction is  $\sigma_2 \sqrt{1 - r_{12}^2}$  which here equals about 14. If  $\lambda_{2,1}$  is negative, this suggests mental deficit. The significance of  $\lambda_{2,1}$  can be assessed by dividing it by its standard deviation. That is, the standard score

$$z = \frac{\lambda_{2,1}}{\sigma_{2,1}} = \frac{\lambda_2 - n - b\lambda_1}{\sigma_2 \sqrt{1 - r_{12}^2}} = \frac{\lambda_2 - 31 - 0.7\lambda_1}{14}$$

Since our interest is confined to mental deficit, a one-tailed test should be used. Then a  $z$  of 1.645 is necessary for the judgment of mental deficit to be significant at the 5 per cent confidence level. In our example, this means that  $\lambda_{2,1}$  would have to be about -23. (The difference  $\lambda_2 - \lambda_1$  can be used to assess mental deficit, but it is not as sensitive as the error of prediction.)

The data presented here are tentative. Before such a procedure can be used with confidence, it will be necessary to expand the sample of test-retest data considerably. It is not clear, for example, how the test-retest correlation varies as a function of time between test and retest. If there is systematic variation, it will be necessary to obtain samples stratified with respect to (1) age at time of first test, and (2) time between test and retest.

It is usually easy to obtain ACB test scores of enlisted men because the scores are recorded on Form 20 panes the enlisted man throughout his career, the retesting of Army enlisted

practice effect and the learning that occurs in an Army environment

TABLE 2 Test retest data on the Army Classification Battery

Test	$\bar{X}_1$	$\bar{X}_2$	$s_1^2$	$s_2^2$	$r_{12}$	$\bar{D}$	$s_d$
<i>Ft. Meade Medical Detachment N = 54</i>							
RV	93	98	504	425	0.80	5	14
AR	89	91	488	596	0.84	2	13
PA	94	98	449	448	0.70	4	16
MA	94	99	336	356	0.81	5	11
ACS	86	88	385	320	0.76	2	13
<i>Walter Reed Hospital Controls N = 47</i>							
RV	99	100	348	426	0.69	1	15
AR	96	97	377	409	0.75	1	14
PA	97	101	539	398	0.66	4	18
MA	100	103	290	327	0.78	3	12
ACS	86	90	364	361	0.70	4	15

Theoretically the variance ( $s^2$ ) of each test should equal 400 since the hypothetical standard deviation is 20. The observed range is from a variance of 290 ( $s = 17$ ) to a variance of 596 ( $s = 25$ ). This seems to be within the variation expected from random sampling. The median test retest correlation is about 0.75 with the hospital sample having somewhat lower correlations than the Ft. Meade group.

One question often raised is whether ACB scores are reliable enough to be worth using. Apparently, in some cases the ACB is administered to subjects who have been subjected to a fair amount of stress, sleep loss, hunger, fatigue, et cetera. However, the median test retest correlation of 0.75 over a period of several years is about as good as can be expected of any group mental test.

There is good internal evidence that, whatever the initial testing conditions may have been, the error variance was not seriously increased. The retest,  $\bar{X}_2$ , was administered to subjects who so far as we know, were not suffering from hunger, sleep loss, fatigue, et cetera. If  $\bar{X}_1$  were full of errors due to stress, then  $s_1^2$  should be much greater than  $s_2^2$ . Inspection of table 2 shows no such consistent difference. As a matter of fact there is little evidence in the literature that sleep deprivation or fatigue (in the amount usually encountered) have much influence on intelligence test scores.<sup>5</sup>

difficulties. The only individuals authorized by Army Regulations to administer the ACB are the Classification Officers stationed on each post. While it is possible to request the Classification Officer to perform the retesting, this would impose an additional workload not anticipated in usual Army situations.

We were granted permission by The Adjutant General to use the ACB for research purposes, provided the usual security precautions were maintained. Presumably, it would be possible for commissioned clinical psychologists (MOS 2232) to request special permission from The Adjutant General. It is also possible that an equivalent form of the ACB could be prepared in co-operation with the Personnel Research Branch (Office of the Adjutant General) for the special use of clinical psychologists.

#### COMPARISON OF ACB WITH WECHSLER BELLEVUE (W B, FORM 1)

One of us (E. H. M.) administered the W B, Form 1, to 100 recruits, ages 20 to 24, at the Ft. Sam Houston Reception Center. Table 3 gives the correlations that were obtained between the W-B and the first three tests of the ACB. From table 3 it can be seen that RV, AR, and PA can be predicted with a validity of about 0.50.

For the convenience of those individuals who are more accustomed to the usual clinical I Q tests than to the Army standard scores and percentiles, approximate equivalence levels have been given in table 4. Table 4 is not based on a sample of subjects who have taken all five tests. It has been deduced from the standardization data available on each test. It is impossible, on the basis of the standardization data, to make any exact transformation of the clinical I Q's into the Army standard scores and percentiles. For this reason, table 4 is not a reliable basis for assessing mental deficit.

If there were data on the correlations between the ACB and the W B where a year or more elapsed before the W B was given, then the same error of prediction technic described previously for the ACB could be used to assess mental deficit. In order to use the W B in the same way as we recommended for the retest ACB, it would be necessary to have large samples stratified by age at time of ACB test and by time interval between ACB and W B.

We are continuing to gather ACB retest data on patients and controls. It is hoped that enough data can be gathered so that adequate norms can be published for the use of the Army Medical Service.

**ACKNOWLEDGMENT** Our thanks are due to Dr. John P. Mundy of the Personnel Research Branch for the use of these data.
